Hepatic secretion and turnover of serum phosphatidylcholine-cholesterol acyltransferase (LCAT) were studied in male and female Sprague-Dawley rats. When serum LCAT activity was measured in fasted and fed male and female rats under conditions designed to reduce the influence of the serum substrate on LCAT activity, this activity (nmol cholesterol esterified/ml serum/hr) was higher in the serum of fed rats (42.1 ± 1.2 and 38.8 ± 1.4 for males and females, resp.) than in the serum of rats fasted for 24 hr (29.2 ± 1.7 and 30.0 ± 1.4, resp.). The differences between sexes were not significant. Total LCAT activity (nmol cholesterol esterified/3-hr incubation) released by perfused isolated livers from fasted rats increased linearly with perfusion time and was significantly ($p<0.01$) higher from female livers than from male livers, with the respective values being 70+ versus 60 at 90 min of perfusion. When LCAT activity was expressed per gram liver, the differences were amplified ($p<0.001$). Perfused livers from fasted male rats pretreated with colchicine (CC, 0.5 mg/100 g i.p.) 3 hr prior to perfusion showed a significantly ($p<0.001$) reduced rate of LCAT output with respect to livers from non-CC-treated males (<10 nmol cholesterol esterified/3-hr incubation at 90 min of perfusion). Pretreatment of fasted rats with CC (0.5 mg, i.p.) resulted in a progressive decrease of serum LCAT activity 0.5, 1, 2, and 4 hr later. The half-life for LCAT activity decay was 13.2 ± 2.5 hr for males and 6.9 ± 0.9 hr for female rats. The fractional turnover rate of about 0.05 hr for males and 0.10 hr for females suggests that the LCAT inactivation rate, or disappearance of LCAT from the serum compartment, was higher in female rats. When CC was added to the serum enzyme at concentrations that might have been reached *in vivo* after drug injection, LCAT activity was unaffected, indicating that CC did not inhibit the enzyme directly.

8001 DISSOLUTION KINETICS OF CHOLESTEROL IN SIMULATED BILE. I: INFLUENCE OF BILE ACID TYPE AND CONCENTRATION, BILE ACID-LECITHIN RATIO, AND ADDED ELECTROLYTE.

(Eng.) Kwan, K. H.; Higuchi, W. I.; Molokhia, A. M.; Hofmann, A. F. (Coll. Pharmacy, Univ. Michigan, Ann Arbor, MI 48109). *J. Pharm. Sci.* 66(8):1094-1101; 1977.

Compressed pellets of cholesterol monohydrate crystals in simulated bile served as a model system for an *in vitro* study of the kinetics of gallstone dissolution as affected by bile acid type and concentration, bile acid:lecithin molar ratio, and electrolytes. The four bile acids were cholyltaurine, cholylglycine, chenodeoxycholyltaurine, and chenodeoxycholylglycine. Bile acid:lecithin molar ratios in bile samples from normal subjects and gallstone patients vary over a wide range, but the ratios produced by 23.2 mM bile acid-6.4 mM lecithin and 46.4 mM bile acid-12.8 mM lecithin were considered representative. The electrolytes used were sodium chloride (0.1-0.5 M) and calcium chloride (0.025-0.10 M). The pH of the simulated bile was maintained at 7.40 by 0.01 M sodium phosphate. The dissolution kinetics of a nonionic, inert solid such as the gallstone is affected by diffusion-convection mass-transfer resistance and interfacial resistance. For almost all the experimental conditions, interfacial resistance was the dominant rate-determining factor in the dissolution of the synthetic gallstone. Comparison of the variables used in this study with those of published reports of human bile samples leads to the conclusion that interfacial resistance dominates over diffusion-convection resistance under certain *in vivo* conditions.

8002 CHOLESTEROL GALLSTONE DISSOLUTION RATE ACCELERATORS. I: EXPLORATORY INVESTIGATIONS

(Eng.) Kwan, K. H.; Higuchi, W. I.; Molokhia, A. M.; Hofmann, A. F. (Coll. Pharmacy, Univ. Michigan, Ann Arbor, MI 48109). *J. Pharm. Sci.* 66(8):1105-1108; 1977.

Various compounds that might function as dissolution accelerators for cholesterol gallstones were studied. The dissolution rates of cholesterol monohydrate pellets in synthetic bile (116 mM sodium cholate, 32 mM lecithin) containing the tested agent at various concentration levels were determined. In the absence of any dissolution rate accelerator, the dissolution kinetics for cholesterol were previously found to be interfacial resistance-controlled, and the rates were approximately 20 times less than the diffusion-controlled rates in the present experiments. Primary, secondary, and tertiary amines and quaternary ammonium compounds were effective accelerators. When the alkyl chain lengths were long enough and/or when the agent concentrations were high enough, the dissolution rates generally approached diffusion-controlled rates. Steroidal amines generally had good activity. Anionic and nonionic surfactants had little or negative activity.

8003 EFFECT OF CHOLESTEROL FEEDING AND ESTROGEN TREATMENT ON SYNTHESIS OF FATTY ACIDS IN LIVER.

(Eng.) Srinivasan, K.; Pynadath, T. I. (Dept. Chemistry, Kent State Univ., Kent, OH 44242). *Atherosclerosis* 27(4):407-417; 1977.

The changes in fatty acid (FA) synthesis in the liver mitochondria, microsomes, and cytoplasm of control rabbits and rabbits fed a diet containing 1% cholesterol to induce atherosclerosis were investigated. Since estrogen inhibits atherosclerosis, some of the cholesterol-fed rabbits were given 1.4 mg estradiol benzoate, s.c., on alternate days. Animals were sacrificed at the beginning of the study and at the end of 3, 6, and 9 weeks. FA synthesis was determined by the incorporation of [1-^{14}C]acetyl coenzyme A or [2-^{14}C]malonyl coenzyme A into long-chain FA under optimal conditions. Atherosclerosis was graded by the degree of aortic involvement, and it increased steadily in cholesterol-fed rabbits over the 9-week study. Cytoplasmic FA synthesis is decreased markedly with increase in atherosclerosis. Mitochondrial FA synthesis was not affected, and there was a small decrease in microsomal FA synthesis. In rabbits given estrogen and cholesterol, cytoplasmic FA synthesis decreased during the first 3 weeks, and then increased, so that at the end of 9 weeks, rate was almost the same as that of controls. After a brief lag period, estrogen apparently counteracts the inhibitory effect of atherosclerosis on cytoplasmic FA synthesis in the liver. Liver FA synthetase is possibly one of the enzyme systems through which estrogens exert their atherosclerosis-retarding effect.

8004 EFFECT OF ETHYNYLESTRADIOL ON BILIARY EXCRETION OF BILE ACIDS, PHOSPHATIDYLCHOLINES, AND CHOLESTEROL IN THE BILE FISTULA RAT.

(Eng.) Kern, F., Jr.; Eriksson, H.; Curstedt, T.; Sjovall, J. (Univ. Colorado Medical Center, 4200 East Ninth Ave., Denver, CO 80220). *J. Lipid Res.* 18(5):623-634; 1977.

The effects of ethynylestradiol (EE, 1 mg/kg/day) on endogenous bile acids, their capacity to conjugate and excrete i.v. infused cholic acid, the concentrations of biliary cholesterol and lecithin, and the individual molecular species of phosphatidylcholine were determined in bile fistula of male and female Sprague-Dawley rats. Eleven endogenous bile acids were identified by gas-liquid chromatography/mass spectrometry, but several minor bile acids, primarily muricholates, could not be completely characterized. After 5 days of EE treatment, the percentage of cholic acid decreased and the percentage of 6β-hydroxylated bile acids, including several monounsaturated species, increased; there was also a decrease in bile acid-independent bile flow. Cholic acid infusion (1.28 μmol/min/100 g) caused cholestasis in control animals but, after EE treatment, cholestasis developed at 0.43 μmol/min/100 g, indicating a lowered threshold for bile acid-induced cholestasis. In the EE-treated rats, there was a slight increase in excretion of unconjugated endogenous bile acids, and a striking impairment of conjugation of i.v. administered cholic acid. An increased concentration of biliary phospholipids in untreated male rats was one of the few sex-related differences observed. Both phospholipid and cholesterol concentrations in the bile were higher in the EE-treated animals. The molar percentage of cholesterol was always 1-2%, but it was slightly higher in treated animals, especially males. EE treatment also affected biliary phospholipid, causing a marked increase of phosphatidylcholine species containing palmitic and oleic acid residues and a decrease of species containing stearic and linoleic acid residues. Infusion of EE alone or with cholic acid caused no increase in biliary excretion of long chain polyunsaturated species. Some of these EE-induced changes in biliary bile acid and lipid excretion are probably peculiar to the rat, but others, such as the increase in molar percentage of cholesterol and cholestasis, may be relevant to disorders in man, especially cholesterol gallstones and idiopathic cholestasis of pregnancy.

8005 ENERGY METABOLISM AND THE CONTROL OF HEPATIC GLYCOGEN TURNOVER BY HORMONES.

(Ger.) Jakob, A. F. (Kantonsspital Zurich, Ramistrasse 100, CH-8091 Zurich, Switzerland). *Fortschr. Med.* 95(31):1923-1926; 1977.

The relationship between energy metabolism and hormonal regulation of hepatic glycogen turnover was studied in perfused rat liver *in vitro*. Cyanide and iodine acetate potentiated glycogen metabolism additively. The glucagon-stimulated production of cyclic AMP (cAMP) was inhibited by iodine acetate. Therefore, activation by inhibitors appears to be cAMP-independent. The acceleration of glycogenolysis paralleled the reduction of tissue ATP levels caused by oxidative phosphorylation and/or glycolysis. These findings suggest a relationship between the increased energy metabolism and enhanced glycogen metabolism. Enhanced glycogenolysis is based on the conversion of phosphorylase b into a; this conversion occurs during activation by inhibitors. It can be assumed that the increase in cellular phosphorylase a is due not only to stimulated activation but also to an inhibition of inactivation. The effect of cyanide and iodine acetate could thus be explained as a result of the inhibition of phosphorylase phosphatase. In the presence of epinephrine, stimulation of both the α and β receptors had a glycogenolytic effect, but the effect of the α-adrenergic component was more pronounced. The β-receptor-mediated effect and that of cAMP were identical, but the α-adrenergic effect occurred by an unknown mechanism. Additional research is necessary to clarify the epinephrine effect on hepatic metabolism.

8006 VASOPRESSIN AND CANINE HEPATIC ARTERIAL BLOOD FLOW. (Eng.) Kerr, J. C.; Reynolds, D. G.; Swan, K. G. (New Jersey Medical Sch., 100 Bergen St., Newark, NJ 07103). *J. Surg. Res.* 23(3):166-171; 1977.

The effects of logarithmically increasing doses of vasopressin (VP), injected via the hepatic artery, on hepatic arterial blood flow (HABF) in dogs were investigated to determine the possible ischemic hazard to the liver by this agent. At 5 x 10^{-5} to 5 x 10^{-2} U/kg, VP produced a dose-dependent diminution in HABF. Control values of HABF (294 ± 32 ml/min), arterial pressure (AP, 126 ± 3 mm Hg), and portal venous pressure (PVP, 8.4 ± 1.0 mm Hg) were not changed significantly by the injection of 5 x 10^{-5} U/kg VP. However, 5 x 10^{-2} U/kg VP reduced HABF by 199 ± 43 ml/min, increased AP by 13 ± 2 mm Hg, and reduced PVP by 1.8 ± 0.2 mm Hg. When VP was infused intra-arterially at a concentration of 5 x 10^{-3} U/kg/min, it reduced HABF to 206 ± 30 ml/min within 1 min; however, HABF gradually returned to near control values (258 ± 24 ml/min) at 5 min. During infusion, AP increased by 10 mm Hg at 6 min and remained elevated throughout the infusion. The PVP was reduced to 6.0 ± 0.9 mm Hg at 9 min. These observations indicate that VP is a potent constrictor of the hepatic artery when it is administered intra-arterially. However, this vasoconstrictor effect is transient; it is characterized by autoregulatory escape, which promptly restores the HABF to control values within minutes. Assuming that the human hepatic artery will respond similarly, it is suggested that the clinical use of VP to control upper gastrointestinal bleeding is unlikely to pose any threat of significant ischemia to liver. The suggested clinical dose for man is 5 x 10^{-3} U/kg/min.

8007 INFLUENCE OF NORETHINDRONE ON DRUG-METABOLIZING ENZYMES OF FEMALE RAT LIVER IN VARIOUS B-VITAMIN DEFICIENCY STATES. (Eng.) Wade, A. E.; Evans, J. S. (Sch. Pharmacy, Univ. Georgia, Athens, GA 30602). *Pharmacology* 15(4):289-301; 1977.

The activities of four drug metabolizing female rat liver enzymes, cytochrome P-450 (CP-450), NADPH cytochrome c reductase (NADPH-CcR), ethylmorphine *N*-demethylase (EMD), and aniline hydroxylase (AH), were measured in female Sprague-Dawley rats fed diets high or deficient in vitamin B and given the oral progestational contraceptive, norethindrone (NE). Rats were fed laboratory chow or synthetic diets deficient in or containing 20 μg/g thiamine, 50 μg/g riboflavin, or 50 μg/g pyridoxine, and they were given 1.0 or 10 mg/day NE by p.o. intubation. After 21 days, the animals were weighed and killed, their livers were weighed, and the enzyme kinetics were measured. Regardless of diet, NE caused loss in body weight and a relative gain in liver weight. In all animals, NE produced either no change or a slight depression of CP-450 and no change or an increase in NADPH-CcR and EMD activity. NE induced AH activity in all rats except those on diets deficient in thiamine or riboflavin. The results demonstrate that B vitamins affect the drug metabolizing enzyme system of the liver with and without administration of NE.

8008 MECHANISM OF OESTROGEN AND PROGESTERONE EFFECTS ON LIPID AND CARBOHYDRATE METABOLISM: ALTERATION IN THE INSULIN:GLUCAGON MOLAR RATIO AND HEPATIC ENZYME ACTIVITY. (Eng.) Mandour, T.; Kissebah, A. H.; Wynn, V. (St. Mary's Hosp., London W.2, England). *Eur. J. Clin. Invest.* 7(3): 181-187; 1977.

To investigate whether altered insulin and glucagon secretion participate in the metabolic changes associated with the intake of female gonadal steroids, the effects of 17β-estradiol (E) and progesterone (P) on the hepatic portal vein blood levels of insulin and glucagon were determined in ovariectomized Wistar rats. To relate the changes in secretory ability of the pancreatic alpha and beta cells to the altered hepatic activity associated with steroid intake, the simultaneous status of both the rate-limiting enzymes and the metabolic intermediates of hepatic lipogenesis and gluconeogenesis were determined following stimulation of glucagon secretion with alanine (1 mmol/kg). Plasma triglycerides increased and plasma glucose fell in fasting rats given E, but not in those given P. E-treated rats had reduced levels of both insulin and glucagon in portal vein blood samples; the insulin/glucagon molar concentration ratio increased indicating a relatively greater decrease in glucagon. P increased portal vein insulin and glucagon but did not alter the insulin/glucagon molar ratio. Glucagon secretion after alanine was enhanced in rats treated with P, whereas E suppressed the glucagon-secreting activity of the pancreas. E increased the activities of the liver lipogenic enzymes, acetyl coenzyme A carboxylase and fatty acid synthetase, and decreased the activity of the gluconeogenic rate-limiting enzyme phosphenol-pyruvate carboxylkinase (PEPCK). When gluconeogenesis intermediates (e.g., phosphenol pyruvate, pyruvate, and glucose-6-phosphate) in the liver were measured, it was evident that gluconeogenesis was inhibited at the PEPCK level. P did not alter the lipogenic or gluconeogenic enzyme activities in the liver. In ovariectomized rats, E reduces the activity of both alpha and beta cells of the pancreas and increases the relative insulin/glucagon molar ratio in portal vein blood. The observed changes in liver enzymes, plasma triglycerides, and glucose could be secondary to this effect.

8009 LACK OF HEPATIC ENZYMATIC ADAPTATION TO LOW AND HIGH LEVELS OF DIETARY PROTEIN IN THE ADULT CAT. (Eng.) Rogers, Q. R.; Morris, J. G.; Freedland, R. A. (Dept. Physiological

Sciences and Animal Science, Univ. California, Davis, CA 95616). *Enzyme* 22(5):348-356; 1977.

The activities of three urea-cycle enzymes and several nitrogen catabolic, gluconeogenic, and lipogenic enzymes were measured in the liver of adult cats fed a commercial kibble or a 17.5% or 70% protein-purified diet, or starved for 5 days. Dietary protein level did not significantly affect hepatic enzyme activities except for tyrosine transaminase activity. It was significantly lower ($p<0.05$) in cats fed the low-protein diet than in cats fed the high-protein diet (0.07 ± 0.03 μmol/min/g liver for the 17.5% protein diet versus 0.22 ± 0.04 for the 70% protein diet). The effects of starvation were insignificant and minimal in comparison with the starvation-induced changes in hepatic enzyme activity reported previously in the rat. These results indicate that the cat may have only minimal capabilities for enzyme adaptation compared with those found in many herbivores and omnivores. They may explain the unusually high protein requirement of cats in comparison with many other animals.

8010 EFFECT OF AFLATOXIN B_1 ON HEPATIC POLYRIBOSOMES AND PROTEIN SYNTHESIS IN THE RAT.

(Eng.) Sidransky, H.; Verney, E.; Murty, C. N.; Sarma, D. S. R.; Reid, M. (George Washington Univ. Medical Center, 2300 I St., N.W., Washington, DC 20037). *Chem. Biol. Interact.* 18(1):69-82; 1977.

The effect of aflatoxin B_1 (AFB_1) on protein synthesis was studied in rat liver. The effect of AFB_1 (6.0 mg/kg) on hepatic polyribosomes (free and membrane-bound), protein synthesis *in vitro*, and initiation factor activity of rats within 3-12 hr was investigated. AFB_1 rapidly led to disaggregation of free and membrane-bound polyribosomes and to the inhibition of *in vitro* protein synthesis by both populations of polyribosomes. It had little or no effect on the activities of initiation factors. Defective ribosomes, particularly the 60S ribosomal subunits, of both types of polyribosomes were observed after treatment. Comparative studies on the effects of AFB_1 and actinomycin D revealed progressive disaggregation by both hepatic free and membrane-bound polyribosomes after AFB_1 but only of the free polyribosomes after actinomycin D. The results are compatible with the suggestion that the action of AFB_1 on the inhibition of protein synthesis is at two levels, at the translational level as an early effect and also at the transcriptional level as a later effect.

8011 INHIBITION OF PROTEIN SYNTHESIS BY ETHANOL IN ISOLATED RAT LIVER PARENCHYMAL CELLS.

(Eng.) Morland, J.; Bessesen, A. (Inst. Medical Biology, Univ. Tromso, N-9001 Tromso, Norway). *Biochim. Biophys. Acta* 474(2):312-320; 1977.

The effects of ethanol on protein metabolism were studied in isolated rat liver hepatocytes. The cells (0.8×10^6-5.0×10^6/ml) were incubated at 37 C in the absence or in the presence of 50 mM ethanol. The incorporation of L-[U-^{14}C]valine and L-[3,5-$^3H_2$] tyrosine into both stationary cell protein and proteins released into the medium was reduced by ethanol incubation. This effect was not caused either by reduced uptake of labeled valine or by diminished specific radioactivity of the precursors; the effect was present in amino acid-free media, suggesting that the possible effects of ethanol on uptake of other amino acids is an unlikely explanation of the reduced incorporation. Instead, ethanol probably affects the protein synthesizing machinery of the liver cells. No effects of ethanol were found when liver cell proteins were prelabeled with L-[U-^{14}C]-valine and the radioactivity remaining in the protein after inhibition of further protein synthesis with cycloheximide (5 μg/ml) was measured. In other prelabeling experiments performed without cycloheximide, ethanol did not affect the amount of radioactive valine remaining within and released from liver protein. It is concluded that ethanol reduces hepatocyte protein synthesis without affecting protein degradation. Hepatocytes appear more sensitive to this effect of ethanol than do intact liver preparations, when the present observations are compared with previous results.

8012 DETERMINATION OF PROTEIN SYNTHESIS ELONGATION FACTOR ACTIVITY IN LIVER BIOPSY SPECIMENS FROM NORMAL AND CIRRHOTIC RATS.

(Eng.) Gressner, A. M.; Greiling, H. (Medical Faculty, Rheinisch-Westfalische Technische Hochschule, Goethestrasse 27-29, 51 Aachen, W. Germany). *Digestion* 15(4):348-352; 1977.

The polypeptide-chain elongation promoting activity (elongation factors 1 and 2) was determined in the 100,000 x *g* cytosol fraction of liver biopsy specimens obtained from six normal and six thioacetamide-induced cirrhotic rat livers. The activity of elongation factors 1 and 2 was tested by their capacity to support the ribosome-dependent poly(U)-directed polymerization of ^{3}H-phenylalanine. Enzyme activity was reduced significantly (by 50% based on tissue wet weight; by 60%, based on DNA concentration) in the cirrhotic liver fractions. Thioacetamide did not inhibit the incorporation of phenylalanine by normal rat liver ribosomes; at 0.0-13.4 μmol thioacetamide, incorporation was 258-243 pmol phenylalanine/100 pmol ribosomes. Because of the cellular heterogeneity in liver cirrhosis, the lowered activity of the elongation factors cannot be ascribed to a single cell type, i.e., the hepatocyte. Further cell-type differentiated analyses are recommended.

8013 UPTAKE AND DEGRADATION OF CHOLESTEROL ESTER-LABELLED RAT PLASMA LIPOPROTEINS IN PURIFIED RAT HEPATOCYTES AND NONPARENCHYMAL LIVER CELLS.

(Eng.) Drevon, C. A.; Berg, T.; Norum, K. R. (Sch. Medicine, Oslo Univ., Blindern, Oslo, Norway). *Biochim. Biophys. Acta* 487:122-136; 1977.

This preliminary study was designed to evaluate whether purified rat hepatocytes and nonparenchymal liver cells are able to take up and degrade cholesterol ester from plasma lipoproteins. Male Wistar rats were inoculated i.v. with 0.5-1.0 ml of plasma containing $[^3H]$cholesterol-labeled cholesterol ester. Collagenase perfusions of the liver were started 5, 15, 45, and 60 min later, and purified hepatocytes and nonparenchymal cells were prepared by differential centrifugation. Labeled free cholesterol and cholesterol ester were measured in purified cells, blood, and liver homogenates (blood samples were withdrawn immediately before the initiation of perfusion). Labeled total cholesterol accumulated rapidly in the liver during the first 5 min after injection, but thereafter, hepatic uptake occurred at a slower rate. After 5 and 60 min, the uptake corresponded to 4.5% and 10%, resp., of the injected labeled lipoproteins. The liver contained 58% labeled free cholesterol (% of labeled total cholesterol) after 5 min and 71% after 1 hr. The amount of total cholesterol was almost 1.5 times higher in purified hepatocytes than in nonparenchymal cells. These data indicate that the hepatic intake of cholesterol ester-labeled lipoproteins was considerable and that both hepatocytes and Kupffer cells participate in this uptake.

8014 EVIDENCE THAT A SEPARATE PARTICLE CONTAINING B-APOPROTEIN IS PRESENT IN HIGH-DENSITY LIPOPROTEINS FROM PERFUSED RAT LIVER.

(Eng.) Fainaru, M.; Felker, T. E.; Hamilton, R. L.; Havel, R. J. (Hadassah Medical Sch., Jerusalem, Israel). *Metabolism* 26(9):999-1004; 1977.

High-density lipoproteins (HDL, 1.075 g/ml<density< 1.175 g/ml) from perfusates of Long-Evans rat liver, unlike those from rat blood plasma, contained protein with the properties of B-apolipoprotein. This protein remained near the origin upon electrophoresis in polyacrylamide gels containing sodium dodecyl sulfate, had β electrophoretic mobility in agarose gel, was insoluble in tetramethylurea, and precipitated with antisera to the B-apoprotein isolated from low-density lipoprotein. The B-apolipoprotein in HDL from rat liver perfusates bound to concanavalin-A Sepharose and thus could be separated from the characteristic HDL, the chemical and physical properties of which are otherwise preserved. These observations suggest that in addition to the discoidal lipoproteins, another particle that contains B-apoprotein exists in the HDL of rat liver perfusates.

8015 THE EFFECT OF DIETARY AMINO ACID IMBALANCE ON SOME RAT LIVER LIPIDS.

(Eng.) Popescu, A.; Croitorescu, L.; Farcasiu, M. (Inst. Medicine and Pharmacy, Bd. Petru Groza S., Bucharest, Rumania). *Rev. Roum. Biochim.* 14(1):51-54; 1977.

The influence of two types of dietary amino acid imbalance on total hepatic lipids, triglycerides, and cholesterol levels were studied in rats. The first diet consisted of gelatin (12%) and casein (8%). The second type of imbalance was induced by feeding a diet containing 0.36% threonine and 8% casein. The first diet induced a decrease in all hepatic lipids studied, as well as growth retardation. The second diet did not influence the liver lipid concentration and produced a lower growth retardation. The nature of a dietary amino acid imbalance affects the liver lipid concentration as well as growth rate.

8016 EFFECT OF DIETARY COMPOSITION ON HEPATIC LIPID ACCUMULATION OF RATS WITH CHRONIC ETHANOL INTAKE.

(Eng.) Chen, N. S. C.; Chen, N. C.; Johnson, R. J.; McGinnis, J.; Dyer, I. A. (Dept. Animal Sciences, Washington State Univ., Pullman, WA 99163). *J. Nutr.* 107(6):1114-1119; 1977.

Diets higher in carbohydrate, fat, or protein (diets 1, 2, and 3, resp.) were formulated isoenergetically with or without ethanol to study their effects on the accumulation of hepatic total lipids in Sprague-Dawley rats fed for 8 weeks. Ethanol ingestion (20% *ad libitum* for 1 week, 30% for 7 weeks) did not affect body weight gain of rats fed diet 1, but diets 2 and 3 resulted in decreased weight gain compared to pair-fed controls. These body weight changes between control and ethanol groups were significant 2 weeks after the treatment was started ($p<0.05$ for diet 2, $p<0.01$ for diet 3). Ethanol administration did not change hepatic weights of rats fed diet 1, but increased hepatic weights of rats fed diets 2 and 3 ($p<0.05$ in both cases). Higher protein alone in the diet increased liver weight. Ethanol intake increased the hepatic total lipid content of rats fed diets 2 and 3 ($p<0.05$ in both cases), but it did not affect those fed diet 1 compared to their pair-fed controls. Weight gain, liver weight, and hepatic total lipids consistently showed that rats consuming 39% wheat starch as carbohydrate were not adversely affected by ethanol ingestion, but those groups fed higher fat or higher protein with ethanol were adversely affected.

8017 LIPID ACCUMULATION IN THE LIVER OF RATS FED A LYSINE-DEFICIENT DIET.

(Eng.) Aoyama, Y.; Kondo, H.; Ashida, K. (Lab. Nutritional Biochemistry, Nagoya Univ., Furo-cho, Chikusa, Nagoya, Japan). *Nutr. Rep. Int.* 14(6):641-655; 1976.

The mechanism responsible for the development of fatty livers in young rats fed a lysine-deficient diet was investigated. A basal diet (amino acid mixture, 7.17%; salt mixture, 4.0%; $NaHCO_3$, 0.14%; vitamins, 0.85%; choline-Cl, 0.15%; corn oil, 5.0%; sucrose, 82.43%) or a lysine-deficient (LD) diet (lysine in amino acid mixture lowered 50%) was fed to male Donryu rats for 10, 20, or 30 days. Liver lipid values were higher in rats on the LD diet than in those on the basal diet at 10 and 20 days, but at 30 days, the values were similar. Similar effects were noted when 5% lard or 5% safflower oil was substituted for corn oil in the LD diet. Rats were fed basal or LD diets for 10-14 days, and incorporation of radioactive acetate (3.5 μCi/0.7 ml 0.9% NaCl/100 g) into liver and body lipids (except blood and liver) and respiratory CO_2 were measured. Total radioactivity of liver and body lipids tended to be lower in rats on LD diets, indicating that increased lipid synthesis was not responsible for the fatty livers. The protein content of the β-lipoproteins and the triglyceride content of the sera were lower in LD-fed rats than in rats on the basal diet, leading to the conclusion that decreased transport of lipids from the liver into the blood might be responsible for excessive liver lipid accumulation in rats on LD diets.

8018 HEPATIC EFFECT OF TWO HYPOLIPIDEMIC DRUGS IN RATS.

(Eng.) Magnusson, G.; Magnusson, O. (Astra Lakemedel AB, Res. and Development Lab., 151 65 Sodertalje, Sweden). *Exp. Pathol.* 13(2/3): 180-187; 1977.

The effects of the hypolipidemic agents 3,9-di-3-pyridyl-2,4,8,10-tetraoxaspiro-5,5-undecane (compound A) and 2-(4-dibenzofuranyloxy)-2-methylpropionic acid (compound B) on hepatic microbody proliferation and catalase synthesis were investigated in male Sprague-Dawley rats. The animals were treated p.o. with one of these drugs or with clofibrate for 10 weeks, the daily doses being 250, 300, and 300 mg/kg, resp. All three drugs caused hepatomegaly with a normal microscopic appearance in the liver cells. In rats given compound A, part of some liver cells contained numerous membranes of smooth endoplasmic reticulum. The hepatocytes of the rats treated with compound B or clofibrate showed a marked increase in microbody profiles and elevated catalase activity in comparison to the control animals. The catalase activity in compound B-treated animals was 130% higher than that of controls and about 40% higher than that of the clofibrate-treated animals ($p < 0.001$ and $p < 0.01$, resp.). Neither the microbodies nor the catalase activity were affected by compound A. Hypolipidemic effects were demonstrated with all three compounds, the most potent activity being shown by compound B. The increase in microbodies observed following compound B and clofibrate treatment, but not after compound A treatment, may be due to the fact that compound B is structurally related to clofibrate.

8019 SHORT-TERM HORMONAL CONTROL OF HEPATIC CARBOHYDRATE AND LIPID CATABOLISM.

(Eng.) Hems, D. A. (St. George's Hosp., Medical Sch., Cranmer Terrace, London SW 17 0RE, England). *FEBS Lett.* 80(2):237-245; 1977.

A review is presented of the range of hormones (e.g., glucagon, adrenaline, vasopressin, angiotensin II, and insulin) that can exert rapid catabolic effects on carbohydrate (glycogen metabolism) and lipid metabolism (glyceride metabolism) in the liver. Several of these hormones, e.g., α-adrenergic agonists, vasopressin, oxytocin, and angiotensin II, do not act via the cyclic-monophosphates of adenosine or guanosine; cations may be implicated in the response mechanisms to these hormones. The range of catabolic hormone effects on liver contributes to the multiple rapid alterations required during stress or adaptation. Resolution of the mechanisms underlying the effects of hormones on liver cells should provide insight into regulatory responses in cell membranes and perhaps into endocrine disorders (e.g., diabetes and obesity).

8020 EFFECT OF FASTING AND FEEDING A HIGH-SUCROS FAT-FREE DIET ON THE SYNTHESIS OF HEPATIC GLYCEROLIPIDS IN VIVO AND IN ISOLATED HEPATOCYTES.

(Eng.) Groener, J. E. M.; Van Golde, L. M. G. (Lab. Veterinary Biochemistry, State Univ. Utrecht, Biltstraat 172, Utrecht, Netherlands). *Biochim. Biophys. Acta* 487:105-114; 1977.

Mechanisms involved in the regulation of triacylglycerol (TG) and phospholipid (PL) biosynthesis in the liver were studied in male Wistar rats. The animals were divided into four groups: group 1 was fed a regular diet *ad libitum*, group 2 was fasted for 24 hr, group 3 was fasted for 48 hr, and group 4 was fasted for 48 hr and then refed a high-sucrose, fat-free diet (58.5% sucrose, 16.5% cellulose, 21.1% proteins, salts, and vitamins) *ad libitum* for 24 hr. Next, rats were inoculated i.v. with 2-^{3}H-glycerol (0.25 mCi); after 5 min, the livers were removed, lipids were extracted, and total TG and diacylglycerols (DG) were isolated by thin-layer chromatography. To evaluate whether the features of hepatic lipid synthesis observed *in vivo* are preserved in enzymatically isolated hepatocytes, hepatocytes from the livers of 24-hr-fasted rats were incubated with variety of labeled precursors. Quantitaitve estimations of the amounts of individual lipid classes in the livers of rats kept in different nutritional states showed changes that might be correlated with the different rates of synthesis of the various lipids; 48-hr fasting resulted in a slight decrease of phosphatidylethanolamine (PEA; 61.5 U, compared to 72.5 U in group 1) and an almost 70% reduction of DG and TG. Refeeding increased the content of DG and TG above control values, but decreased PEA content further (49.7 U). Similar changes were detected *in vitro*.

8021 EARLY ALTERATIONS INDUCED BY CARBON TETRACHLORIDE IN THE LIPIDS OF THE MEMBRANES OF THE ENDOPLASMIC RETICULUM OF THE LIVER CELL: I. SEPARATION AND PARTIAL CHARACTERIZATION OF ALTERED LIPIDS.

(Eng.) Benedetti, A.; Casini, A. F.; Ferrali, M.; Comporti, M. (Istituto di Patologia Generale, Universita di Siena, Via Laterino 8, 53100 Siena, Italy). *Chem. Biol. Interact.* 17(2):151-166; 1977.

Carbon tetrachloride induced alterations in the fatty acids of liver microsomal lipids were studied. Thin-layer chromatography of fatty acid methyl esters prepared from liver microsomal lipids of CCl_4-treated rats revealed a component, spot D, with an Rf value (0.66) lower than that (0.80) of the methyl esters, spot M. The spot D lipids showed a marked diene conjugation absorption, but those of spot M showed no absorption of conjugated dienes. Studies with ^{14}C-labeled CCl_4 indicated that compounds in spots D and M contained 28% and 42% of the label, resp. However, the specific activity of spot D [68,475 disintegrations/min (dpm)/mg] was about 1,000 times greater than that of spot M (73.8 dpm/mg). The spot D lipids showed no response when they were analyzed by gas-liquid chromatography with an electron capture detector (ECD), but those of spot M exhibited a response similar to that of unfractionated fatty acid methyl esters. The lack of the ECD response for spot D compounds is probably due to the fact that they cannot be eluted from the column.

8022 MODIFICATION OF CARBON TETRACHLORIDE HEPATOTOXICITY BY CHEMICALS. (Eng.)

Suriyachan, D.; Thithapandha, A. (Faculty Science, Mahidol Univ., Bangkok 4, Thailand). *Toxicol. Appl. Pharmacol.* 41(2):369-376; 1977.

The chemical modification of carbon tetrachloride hepatotoxicity in male New Zealand mice is reported. Hepatic injury induced by CCl_4 (0.5 ml/kg, i.p.), was prevented by phenazine methosulfate (2 mg/kg, i.p., 5 doses at 0.5-hr intervals). *In vitro*, at a concentration of 1×10^{-2} M, this compound noncompetitively inhibited NADPH-cytochrome C reductase by 53%. However, cobaltous chloride (60 mg/kg, s.c., daily for 2 days), which decreased the microsomal cytochrome P-450 content of mouse liver to approximately half of its normal value and reduced ethylmorphine *N*-demethylase and aminopyrine *N*-demethylase activities from control values of 3.40 ± 0.30 and 31.76 ± 2.48, resp., to 1.72 ± 0.24 and 20.63 ± 2.05 nmol formaldehyde formed/mg protein/min, resp., offered no protection against CCl_4-induced liver damage. Cobaltous chloride also slightly reduced aniline hydroxylase activity from a control value of 6.15 ± 0.26 to 4.95 ± 0.26 nmol of *p*-aminophenol/mg protein/20 min and impaired the *in vivo* oxidative metabolism of hexobarbital, as evidenced by a prolongation of sleeping time from a control value of 39 ± 4 to 66 ± 10 min. However, cobaltous chloride had no effect on the rate of reduction of cytochrome P-450 by NADPH. 2-Diethylaminoethyl-2,2-diphenylvalerate (50 mg/kg, i.p.) also failed to protect against CCl_4 hepatotoxicity, although it inhibited the hydroxylation of a number of substrates. This inhibitor, a type I compound, enhanced cytochrome P-450 reduction by NADPH from a control value of 8.21 ± 0.74 to 18.87 ± 0.52 nmol reduced/min/mg protein. These findings are compatible with the hypothesis that cytochrome P-450 is the critical site for CCl_4 activation.

8023 STUDIES ON THE EFFECT OF 3,4-DEHYDROPROLINE ON COLLAGEN METABOLISM IN CARBON TETRACHLORIDE-INDUCED HEPATIC FIBROSIS. (Eng.)

Kerwar, S. S.; Oronsky, A. L.; Choe, D.; Alvarez, B. (Lederle Lab., Pearl River, NY 10965). *Arch. Biochem. Biophys.* 182(1):118-123; 1977.

The effect of 3,4-dehydroproline on collagen metabolism was studied in rats in which hepatic fibrosis was induced by chronic treatment with carbon tetrachloride (0.1 ml/100 g, s.c., twice weekly). The amount of collagen and the specific activity of prolyl hydroxylase were greatly enhanced; prolyl hydroxylase activity in the CCl_4-treated rats ranged between 1.5- and 2.5-fold greater than that in controls. When the fibrotic animals were treated with DL-3,4-dehydroproline (100 mg/kg, i.p.) for 5 consecutive days, the specific activity of liver prolyl hydroxylase was greatly decreased 4.26 ± 0.14 counts per min (cpm)/mg protein $\times 10^{-3}$ and approached the activity observed in the livers of normal rats (3.36 ± 0.14 cpm/mg $\times 10^{-3}$). Although CCl_4 did not affect prolyl hydroxylase activity of the lung, the administration of dehydroproline caused a significant ($p<0.01$) decrease in enzyme activity. Collagen extracted from normal and fibrotic rat livers was analyzed by chromatography on carboxymethylcellulose. Normal rat liver was found to contain α_1 and α_2 chains with chromatographic properties similar to type I collagen of calf skin. Fibrotic liver contained Type I collagen as well as collagen with chromatographic properties similar to Type III. The increase in the latter type of collagen was more pronounced in the livers of fibrotic animals.

8024 TRANSAMINASES OF HEPATIC TISSUE CULTURE CELLS AND THE EFFECT OF CARBON TETRACHLORIDE ON THEIR LEAKAGE. (Eng.)

Watanabe, S.; Hioki, M.; Mohri, T.; Kitagawa, H. (Faculty Pharmaceutical Sciences, Univ. Chiba, Yayoi-cho, Chiba-shi, Chiba, Japan). *Chem. Pharm. Bull. (Tokyo)* 25(5):1089-1093; 1977.

The effect of CCl_4 on the leakage of GOT and GPT from hepatic tissue culture cells (rat hepatoma origin) was studied. The addition of 10 mM CCl_4 to the medium followed by 48 hr of incubation enhanced the leakage of both enzymes into the medium, with the leaking ratio (transaminase activity in medium/transaminase activity in cell) for GOT and GPT being 1.9 and 4.8, resp. Treatment of the cells with 1 or 10 mM CCl_4 for 96 hr also enhanced the leakage of GOT (GPT was not assayed). The increased leaking ratios appeared to be due to an increase in cell membrane permeability to the enzymes and not to a promotion of synthesis or cellular accumulation. Studies of the fluid phase concentration of CCl_4 with time using a model system that consisted of water enclosed in culture bottles indicated that this concentration decreased rapidly with time and that the addition of 10 and 1 mM CCl_4 to the culture medium represented exposure of the cells to 0.2 and 0.02 mM, resp., over most of the incubation period.

8025 LONG-TERM EXPOSURE OF RATS TO HEXACHLOROBENZENE (HCB): INFLUENCE ON PORPHYRIN EXCRETION IN THE URINE AND ON CYTOCHROME P-450 ACTIVITY IN THE LIVER. (Ger.)

Goerz, G.; Krieg, Th.; Bolsen, K.; Lissner, R. (Univ.-Hautklinik Dusseldorf, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany). *Arch. Dermatol. Res.* 259(2):199-206; 1977.

The influence of hexachlorobenzene (HCB, 0.05% of the diet) on urinary porphyrin excretion and hepatic cytochrome P-450 activity was studied in female Wistar rats. Urinary porphyrin excretion remained normal during the first 54 days of treatment, after which the porphyrin, 5-aminolevulinic acid, and porphobilinogen excretions increased sharply and in parallel from day 57 onward. However, the O-dealkylating activity of the liver, determined by the O-dealkylation of 7-ethoxycoumarin, increased significantly as early as day 2 and it exceeded the initial value by over 20 times on day 80. The inhibition of cytochrome P-450 activity by metyrapone, naphthoflavone, tetrahydrofuran, or CO/O_2 did not have the typical inhibition pattern of phenobarbital- or benzopyrene-induced cytochrome P-450. When the animals became porphyric on about day 55, no qualitative changes in the cytochrome P-450 pattern were demonstrable. The relationship between the hepatic enzyme induction and porphyria following HCB administration still remains unclear.

8026 EXPERIMENTAL PORPHYRIAS AS MODELS FOR HUMAN HEPATIC PORPHYRIAS.

(Eng.) DeMatteis, R.; Stonard, M. (Medical Res. Council Lab., Woodmansterne Rd., Carshalton, Surrey, England). *Semin. Hematol.* 14(2):187-192; 1977.

The similarity of experimental models of hepatic porphyrias to the human disease is discussed. In rats, a small dose of 3,5-diethoxycarbonyl-1,4-dihydro-collidine (DDC) produces a biochemical reaction similar to that of variegate-type human acute porphyria in its latent phase. Hexachlorobenzene (HCB) induces a porphyria that closely resembles human chronic hepatic porphyria. Barbiturates and other lipid-soluble drugs can exacerbate the effects of DDC in animals, as they do in patients with genetic porphyria. The role of Fe in the exacerbation of human chronic hepatic porphyria may be elucidated by studies of animals treated with HCB.

8027 LIGHT AND ELECTRON MICROSCOPIC STUDY OF HEMORRHAGIC HEPATITIS INDUCED BY TRIMETHYLLYSINE AND D-GALACTOSAMINE.

(Eng.) Tompa, A.; Lapis, K.; Szende, B. (Semmelweis Medical Univ., Ulloi ut 26, H-1085 Budapest VIII, Hungary). *Exp. Pathol. (Jena)* 13(2/3):118-129; 1977.

The effect of prior treatment with ε-aminotrimethyllysine (TML) on D-galactosamine (DGA)-induced hepatitis in mice was investigated. Previous studies have shown that TML stimulates hepatocyte proliferation in the same way as partial hepatectomy. On the other hand, DGA does not cause hepatitis in newborn or partially hepatectomized animals (i.e., in the regenerating liver). CFLP female mice were given 10 mg/kg TML of 1 g/kg DGA, or TML followed 10 days later by DGA. The mice were killed 18, 24, 48, and 72 hr posttreatment, and their livers were weighed and examined ultrastructurally. The livers of TML-treated mice were similar to those of controls; those of DGA-treated mice showed necrosis, inflammation, and some regeneration. Animals sacrificed 18-24 hr after TML + DGA had severe hemorrhagic hepatitis; there was less liver damage in mice sacrificed at 48-72 hr. The expected result of the administration of both drugs was that TML pretreatment would protect mice against DGA-induced hepatitis, but the pretreatment had the opposite effect. It is proposed that the cell proliferation caused by TML differs from the regeneration induced by partial hepatectomy.

8028 PROTECTIVE EFFECT OF AMMONIUM IONS AND L-NORVALINE ON GALACTOSAMINE INDUCED LIVER INJURY.

(Eng.) Pausch, J.; Wohleb, B.; Gerok, W. (Medizinische klinik der Universitat Freiburg, Hugstetter Strasse 55, D-7800, Freiburg, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 358(5):595-597; 1977.

The effect of ammonium ions and of L-norvaline on galactosamine-induced liver injury was investigated in Wistar rats. The animals received a single i.p. injection of galactosamine (1.85 mmol/kg) 4 hr after receiving the first of eight doses of i.p. ammonium acetate (3.7 mmol/kg). In other experiments, the animals received 5.0 mmol/kg L-norvaline, i.p., at 4 hr and 2 hr before galactosamine administration. The aspartate aminotransferase, alanine aminotransferase, and glutamate dehydrogenase levels in galactosamine-treated controls were 404 ± 234, 505 ± 295, and 181 ± 125 U/l, whereas the levels were 143 ± 58, 85 ± 51, and 24 ± 15 U/l in ammonium plus galactosamine-treated animals and 50 ± 13, 25 ± 6, and 11 ± 6 U/l in L-norvaline plus galactosamine-treated animals. The results indicate that both L-norvaline and ammonium acetate protect against galactosamine-induced liver injury.

8029 ACTIVATION OF α-METHYLDOPA, PARACETAMOL AND FUROSEMIDE BY HUMAN LIVER MICROSOMES.

(Eng.) Dybing, E. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway). *Acta Pharmacol. Toxicol.* 41(1):89-93; 1977.

Experiments were carried out in human liver microsome to determine whether enzyme pathways for the metabolic activation of α-methyldopa, paracetamol, and furosemide are present in humans as well as in laboratory animals. The human liver microsomes were found to have a cytochrome P-450 content of 0.52 nmol/mg protein and a cytochrome b_5 content of 0.25 nmol/mg, i.e., approximately 50-70% of the levels found in laboratory animals. NADPH cytochrome c reductase activity was 95 nmol/mg protein/min. When radiolabeled α-methyldopa, paracetamol, and furosemide were incubated with the microsomes in the presence of NADPH, these compounds were converted to intermediates that bound irreversibly to microsomal protein. The addition of superoxide dismutase (15 μg/ml) or ascorbic acid (1 mM) totally blocked the activation of α-methyldopa. The amounts of drug bound covalently to protein for α-methyldopa, paracetamol, and furosemide were 1.16, 0.55, and 1.68 nmol/mg microsomal protein/10 min, resp. These studies show that enzyme pathways responsible for the metabolic activation of α-methyldopa, paracetamol, and furosemide exist in human liver microsomes.

8030 THE BIOSYNTHESIS OF GLYCOSAMINOGLYCANS IN NORMAL RAT LIVER AND IN RESPONSE TO EXPERIMENTAL HEPATIC INJURY. (Eng.) Gressner, A. M.; Pazen, H.; Greiling, H. (Klinisch-Chemisches Zentrallaboratorium der Med. Fakultat der RWTH, Goethestrasse 27-29, D-5100 Aachen, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 358(7):825-833; 1977.

The synthesis of glycosaminoglycans in slices from normal and thioacetamide (50 mg/kg)-injured rat liver was studied. The rates of incorporation of [^{14}C]glucosamine into specific types of glycosaminoglycans varied markedly; nearly 90% was incorporated into a fraction containing predominantly heparan sulfate and far less if any heparin; about 9.5% was incorporated into chondroitin 4- and 6-sulfate, and only 0.2% of the radioactivity was found in hyaluronic acid. The rate of synthesis of a fraction having several of the characteristics of keratan sulfate comprised only 0.3% of the synthesis of total glycosaminoglycans. No [^{14}C]hexosamine was incorporated into dermatan sulfate. Following acute hepatic injury, the synthesis of glycosaminoglycans was stimulated by 80-100%, and the proportions of various types of these molecules changed. If calculated on the basis of the specific activity of the precursors of glycosaminoglycans, which was found to be strongly reduced in injured liver, the maximum enhancement of total glycosaminoglycan synthesis was 6.6-fold 5 days after the onset of liver injury.

8031 INFLUENCE OF SAMPLING ON DRUG KINETICS IN LIVER PERFUSION. (Eng.) Timmer, C. J.; Wijnand, H. P. (Scientific Development Group, Organon Intl. B. V., Oss, Netherlands). *J. Pharmacokinet. Biopharm.* 5(4):335-358; 1977.

A mathematical treatment of the influence of sampling on drug kinetics in liver perfusion is presented. Based on the derived equations, a Fortran IV computer program (PERFUS) was developed, by which the time course of drug concentrations can be simulated for any sampling scheme. The simulations show that the withdrawal of large samples from the reservoir, i.e., greater than 5% of the reservoir volume, results in substantially biased parameters for drugs that are rapidly distributed and/or metabolized. For the fitting of empirical data, a Fortran IV computer program is presented, based on BMDX85 nonlinear least squares by Gauss-Newton iterations. This program (PERFIT) estimates model parameters corrected as if no sampling had occurred, no matter how distorted the drug disappearance curve may be as a result of sampling or due to degeneration of the two-compartment model into a one-compartment model.

8032 ALTERATION OF HEPATIC MICROSOMAL ENZYME SYSTEMS AND THE LETHAL ACTION OF NON-STEROIDAL ANTI-ARTHRITIC DRUGS IN ACUTE AND CHRONIC MODELS OF INFLAMMATION. (Eng.) Sofia, R. D. (Dept. Pharmacology and Toxicology, Wallace Lab., Cranbury, NJ 08512). *Agents Actions* 7(2):289-297; 1977.

The effect of chronic inflammation due to adjuvant-induced polyarthritis (AIP) on the rat hepatic microsomal enzyme systems was measured indirectly by sodium hexobarbital anesthesia and zoxazolamine paralysis. In addition, drug toxicity studies with meseclazone, acetylsalicylic acid, phenylbutazone, and indomethacin were performed in the polyarthritic rats. Polyarthritis was induced by s.c. injection of 0.1 ml of a 0.5% suspension of heat-killed *Mycobacterium tuberculosis* into the hind paw. Carrageenan edema, a model of acute inflammation, was induced in another group of rats by injection of a 1.0% solution of calcium carrageenan in the hind paw. In the AIP rats, hexobarbital sleeping time was increased by 168.9% and zoxazolamine-induced paralysis was extended by 50.2% on day 14 after injection. Neither of these indications of a depressed hepatic microsomal enzyme system were observed in the carrageenan edema rats. In AIP rats, the LD$_{50}$ values for acetylsalicylic acid, phenylbutazone, and indomethacin decreased as the inflammation became more severe. The LD$_{50}$ of meseclazone, a new nonsteroid anti-inflammatory agent, was not altered in either the AIP or carrageenan edema rats. Chronic inflammation also appears to affect the central nervous system, since sleeping time was increased in AIP rats given sodium barbital, a barbiturate that is excreted without undergoing metabolism in the liver.

8033 CHELATING AGENTS AND HEPATIC DRUG METABOLISM IN THE RAT. (Eng.) Torronen, R.; Alakuijala, P.; Marselos, M. (Dept. Physiology, Univ. Kuopio, SF-70101 Kuopio 10, Finland). *Arch. Int. Pharmacol.* 226(1):11-20; 1977.

The effects of chelating agents on hepatic drug metabolism were studied in male rats, and hepatic Cu, Zn, and Mg contents were measured to detect possible alterations. One week of treatment with dimercaprol (50 mg/kg/day) decreased Cu content and suppressed NADPH-cytochrome *c* reductase, but it enhanced *p*-nitroanisole demethylase and uridine diphosphate (UDP)-glucuronosyltransferase activities. CaNa$_2$EDTA (200 mg/kg/day) decreased the content of Cu and Zn and enhanced the activities of *p*-nitroanisole demethylase and UDPglucose dehydrogenase. Penicillamine (100 mg/kg/day) decreased the Cu level in the total hepatic homogenate and increased the Cu level in the microsomes. The same alterations were observed with Mg, which also accumulated in the microsomes after penicillamine treatment. The microsomal content of Zn was significantly decreased. The *O*-demethylation of *p*-nitroanisole was enhanced, but no other changes in the drug metabolizing enzymes were detected. These results suggest that treatment of rats with chelating agents at doses comparable to those used in humans does not bring about toxic effects as far as the hepatic trace elements and microsomal drug metabolism are concerned. The changes in the trace elements do not correlate with those of the drug metabolizing enzymes.

8034 EXPERIMENTAL HEPATIC INJURY: THE SEQUENTIAL CHANGES IN DRUG METABOLIZING ENZYME ACTIVITIES AFTER ADMINISTRATION OF ACETAMINOPHEN.

(Eng.) Willson, R. A.; Hart, F. E. (Div. Gastroenterology, Univ. Washington, Seattle, WA 98195). *Res. Commun. Chem. Pathol. Pharmacol.* 16(1):59-71; 1977.

Because of the poor correlation reported in liver diseases between *in vitro* drug enzyme activities and standard liver function tests or the degree of necrosis, the sequential changes in the *in vitro* drug metabolizing enzyme activities were investigated in experimental liver injury. Experimental hepatic necrosis was induced in phenobarbital-pretreated rats by the administration of acetaminophen (1,200 mg/kg) in dimethyl sulfoxide (DMSO), i.p. The cytochrome P-450 content and the specific activities of aminopyrine demethylase, aniline hydroxylase, and bilirubin glucuronyl transferase diminished over the 3-day study period, as compared with control animals. The reductions, however, were generally modest, not uniform for all the enzymes assayed, and correlated poorly with histologic necrosis and standard liver function tests. It is concluded that in acute liver disease, changes in the hepatic *in vitro* drug metabolizing enzyme capacity may not be closely related to cellular necrosis, *per se*, and the degree of change in enzyme activities will vary from one enzyme system to another. These findings may explain, in part, the often inconsistent alterations in the disposition and elimination of drugs described in associated liver disease.

8035 PORTACAVAL TRANSPOSITION AND SUBSEQUENT PARTIAL HEPATECTOMY IN THE RAT: EFFECTS ON LIVER ATROPHY, HYPERTROPHY AND REGENERATIVE HYPERPLASIA.

(Eng.) Guest, J.; Ryan, C. J.; Benjamin, I. S.; Blumgart, L. H. (Glasgow Royal Infirmary, Glasgow, Scotland). *Br. J. Exp. Pathol.* 58(2): 140-146; 1977.

Body and liver weights were measured before and after portacaval transposition (PCT) plus left adrenalectomy (A) in Sprague-Dawley rats, and their regenerative hyperplastic responses were measured after partial hepatectomy (PH) performed 3 weeks after PCT. Rats undergoing PCT + A gained significantly less ($p< 0.001$) body weight 3 weeks after surgery (initial and final weights, 210.2 ± 6.9 and 265.3 ± 29.5 g, resp.) than did rats undergoing sham PCT + A (initial and final weights, 210.2 ± 6.7 and 289.5 ± 26.9 g, resp.). Loss of body weight at 3 weeks after PH was significant in rats undergoing PCT + A ($0.05>p>0.025$) and in rats undergoing sham PCT PCT + A ($0.01>p>0.005$). At 3 and 6 weeks after PCT + A, the relative liver weights (% of body weight) were 3.29 ± 0.19 and 2.88 ± 0.23, resp., in nonhepatectomized rats 399 ± 0.32 and 3.64 ± 0.13, resp., in nonhepatectomized rats undergoing sham PCT + A; these differences were significant ($0.005> p>0.001$). Immediately after PH, there were no significant differences in the relative weight of the liver remnant between rats undergoing PCT + A and those undergoing sham PCT + A or A alone. However, the relative liver weight 3 weeks after PH was significantly less in rats undergoing PCT + A (2.47 ± 0.42%) than in rats undergoing sham PCT + A (3.47 ± 0.37%) or in rats undergoing A alone (3.35 ± 0.46%), but it did not differ significantly from the expected relative liver weight found in nonhepatectomized rats 6 weeks after PCT + A (2.88 ± 0.23%). Despite the atrophic changes occurring in the liver of rats undergoing PCT + A, there was no change in the DNA activity ratio of the liver (either in timing or magnitude) in the first 36 hr after partial hepatectomy. This observation suggests that regenerative hyperplasia following PH is not impaired by the diversion of portal blood factors.

8036 EFFECTS OF PARTIAL HEPATECTOMY ON EXTRARENAL ERYTHROPOIETIN PRODUCTION IN RATS.

(Eng.) Anagnostou, A.; Schade, S.; Barone, J.; Fried, W. (Univ. Illinois Coll. Medicine, Chicago, IL). *Blood* 50(3):457-462; 1977.

The effects of partial hepatectomy (50-60%) on extrarenal erythropoietin production were studied in female Sprague-Dawley rats. Rats were either partially hepatectomized or sham-operated. At intervals of from 5 min to 7 days later, both kidneys were removed and the animals were then exposed to hypoxia (0.4 atmospheres of air) for 7.5 hr. Immediately afterward, plasma was collected, and its erythropoietin titer was assayed. Rats that were partially hepatectomized on day 2, 3, or 4 prior to nephrectomy and hypoxia had significantly higher plasma erythropoietin levels (average levels of 0.41 0.17, and 0.16 erythropoietin U/ml plasma, resp.) than sham-operated controls (average, 0.04 erythropoietin U/ml plasma), but rats hepatectomized 5 min, 1 day, or 7 days prior to nephrectomy and hypoxia did not. The average wet liver weight of the sham-operated rats was 5.9 g; 1 day posthepatectomy it had fallen to 3.1 g, and 4 days posthepatectomy it had regenerated to 6.0 g. The erythropoietin titers of nonhepatectomized rats undergoing partial splenectomy (66%) 3 or 4 days prior to nephrectomy and hypoxia and of nonnephrectomized rats undergoing partial hepatectomy 3 or 4 days prior to hypoxic exposure did not differ significantly from those of sham-operated controls. These results are consistent with the conclusion that extrarenal erythropoietin production is enhanced in association with a rapid regeneration of hepatic cells.

8037 REGENERATION OF RAT LIVER IN THE PRESENCE OF ESSENTIAL OILS AND THEIR COMPONENTS.

(Eng.) Gershbein, L. L. (Northwest Inst. Medical Res., 5656 W. Addison St., Chicago, IL 60634). *Food Cosmet. Toxicol.* 15(3):173-181; 1977.

The effects of several essential oils, flavorings, spices, and plant materials on liver regeneration were determined over a 10-day period in partially hepatectomized rats given s.c. injections of high levels of essential oils, terpenes, or aromatic compounds daily for the first 7 days or fed *ad libitum* for 10 days on diets supplemented with oils, spices, and botanicals. The amount of tissue regenerated was increased significantly by the oils of anise, fennel, tarragon, parsley seed, celery seed, and oleoresin; by nutmeg, mace, cumin, and sassafras; and by the aromatic principles 4-allylanisole, 4-propenylanisole, *p*-isopropylbenzaldehyde, safrole, and isosafrole. Most of the essential oils were ineffective in total doses up to 3,000 mg/kg because they contained a high percentage of terpenes, which proved inert. Many of the agents effective by the s.c. route were also active when added to the diet, although a possible exception was tarragon oil (0-50%). Azulenes (e.g., *Matricaria chamomila* L. oils and guaiazulene) stimulated regeneration when given by injection, but Haitian vetivert oil, and the alcohol mixture vetiverol, and guaiene, in massive doses, did not. However, these last three agents, as well as the blue chamomile oils and ground *Matricaria* flowers, stimulated liver regeneration when given in the diet. Several of the test agents also increased the wet and dry liver weight expressed relative to body weight, in intact rats, whether given s.c. or p.o.

8038 FIBRINOLYSIS AND LIVER REGENERATION. (Eng.) Rixon, R. H.; Walker, P. R.; Whitfield, J. F. (Div. Biological Sciences, Natl. Res. Council Canada, Ottawa, Canada K1A 0R6). *J. Cell. Physiol.* 92(1):13-21; 1977.

Plasmin and plasminogen activator proteases were investigated as potential blood-borne mediators of the hepatectomy-induced proliferation of hepatocytes in male Sprague-Dawley rats. Partial (68%) liver resection, which activated the proliferation of the remaining hepatocytes, also doubled the level of circulating plasminogen activator within 30 min. However, this level was greatly depressed 2 hr after partial resection, with the depression lasting 8-10 hr before a return to normal levels 2-4 hr before the remaining hepatocytes began to synthesize DNA. This sequence of changes in the fibrinolytic potential of the blood was not abolished by prior thyroparathyroidectomy that inhibits the initiation of hepatocyte DNA synthesis and prevents the secretion of calcium homeostatic hormones, another early systemic consequence of partial liver resection. Since the early rise in plasminogen activator activity did not cause the appearance of active (free) circulating plasmin and since injection of the fibrinolysis and protease inhibitors ε-aminocaproic acid (30 mg/100 g/injection) and Trasylol (2,500 kallikrein-inhibiting U/100 g/injection) into the rats before and within 80 min after partial hepatectomy did not prevent hepatocytes from initiating DNA synthesis, it is unlikely that plasmin or its activator protease are blood-borne initiators of hepatocyte proliferation.

8039 EFFECTS OF Salmonella enteritidis ENDOTOXIN ON THE EXCRETORY FUNCTION OF THE ISOLATED PERFUSED RAT LIVER. (Eng.) Utili, R.; Abernathy, C. O.; Zimmerman, H. J. (I Facolta di Medicina, Universita di Napoli, Via Cotugna 1, Napoli 80135, Italy). *Proc. Soc. Exp. Biol. Med.* 155(2):184-188; 1977.

The effects of lipopolysaccharide (LPS) from *Salmonella enteritidis* on the excretory function of isolated perfused rat liver (IPRL) were studied. The addition of 40 and 60 μg/ml LPS extracted with trichloracetic acid (Boivin type) to the perfusate reduced bile flow from a control value of 1.40 ± 0.03 to 1.15 ± 0.02 and 1.05 ± 0.05 μl/min/g liver, resp. ($p<0.01$). Boivin LPS also significantly ($p<0.01$) reduced the rate of indocyanine green (ICG) excretion from a control value of 5.43 ± 0.16 to 3.75 ± 0.24 and 3.47 ± 0.30 μg/min/g liver, resp. The ICG concentration in the bile was also increased, but ICG uptake from the perfusate was not affected. The addition of 40 μg/ml Boivin LPS decreased bile flow (from 1.30 ± 0.02 to 1.14 ± 0.01 μl/min/g bile acid liver, $p<0.05$), and bile acid excretion (70.3 ± 2.7 versus 54.0 ± 0.8 μmol/min/g liver, $p<0.05$). However, bile acid concentration in the bile was unchanged. When BSP was infused into the IPRL 15 min after the addition of 20 μg/ml LPS extracted with phenol-water (Westphal type), bile flow was significantly ($p<0.01$) reduced from a control value of 1.85 ± 0.05 to 1.48 ± 0.08 μl/min/g liver. BSP excretion was also significantly ($p<0.05$) reduced from 20.1 ± 1.1 to 15.4 ± 1.0 μg/min/g liver. The BSP transport maximum was reduced by 23% ($p<0.05$), but the BSP concentration in the bile was unchanged. Since two LPS preparations were used, it is suggested that the effects were due to a biological property of the endotoxin and not to contaminants produced by extraction. LPS had no effect on the perfusate flow rate or on the rate of aspartate aminotransferase release by the IPRL. Thus, inhibition of hepatic excretory pathways is a biological activity of LPS, and the data are consistent with the theory that impairment of hepatic excretion by bacterial endotoxins might play a role in the pathogenesis of the cholestatic jaundice in gram-negative bacterial infections.

8040 ROLE OF ZINC IN THE ABATEMENT OF HEPATOCELLULAR DAMAGE AND MORTALITY INCIDENCE IN ENDOTOXEMIC RATS. (Eng.) Sobocinski, P. Z.; Powanda, M. C.; Canterbury, W. J.; Machotka, S. V.; Walker, R. I.; Snyder, S. L. (U.S. Army Medical Res. Inst. Infectious Diseases, Fort Detrick, Frederick, MD 21701). *Infect. Immun.* 15(3):950-957; 1977.

The effectiveness of Zn against *Salmonella typhimurium* endotoxin-induced mortality and hepatocellular damage was studied in male Fischer-Dunning rats. Pretreatment 1 hr prior to i.p. challenge with endotoxin with $ZnCl_2$ (0.4-2.0 mg/100 g body weight, i.p.) resulted in 80-100% survival, compared with 10% survival in untreated control rats, 24 hr after endotoxin treatment. At >2.0 mg/100 g, $ZnCl_2$ was toxic and provided diminished protection. I.v. administration of Zn did not provide protection. When Zn was given after endotoxin, its ability to enhance survival was greatly reduced as a function of time after endotoxin. Plasma ornithine carbamoyltransferase activity was measured and liver sections were examined histologically to determine the extent of liver damage. Endotoxin absorption from the peritoneal cavity and hepatic uptake were studied by using ^{51}Cr-labeled endotoxin. Zn pretreatment (1.6 mg/100 g) significantly reduced the ^{51}Cr-labeled endotoxin content of blood (314 ± 58 counts/min [cpm]/ml) and liver (427 ± 109 cpm/g), compared to untreated controls (1,137 ± 131 cpm/ml and 2,547 ± 360 cpm/g, resp.; $p<0.001$). It also prevented endotoxin-induced elevations in plasma ornithine carbamoyltransferase activity ($p<0.01$) and hepatic tissue necrosis. It is suggested that the protection afforded by i.p. Zn is due to its ability to diminish absorption of the toxin from the peritoneal cavity and subsequent hepatic uptake.

8041 EFFECT OF ANOXIA AND ATP DEPLETION ON THE MEMBRANE POTENTIAL AND PERMEABILITY OF DOG LIVER.

(Eng.) Lambotte, L. (Univ. Louvain, Lab. Experimental Surgery, 1200-Brussels, Belgium). *J. Physiol. (Lond.)* 269(1):53-76; 1977.

The mechanisms responsible for the depolarization of the hepatocytes secondary to anoxia were studied in the isolated perfused dog liver. The role of the inhibition of the sodium pump following exhaustion of the energy reserves and of the modifications of membrane permeability was elucidated. Anoxia was compared with ouabain and with a reduction of the cellular ATP level with respect to induction of depolarization. Membrane potentials were measured with microelectrodes. Potassium, sodium, and chloride were determined in plasma samples and liver tissues. The extracellular space was measured with tritiated inulin or by an electrical impedance method. Adenine nucleotides were also measured in liver biopsies. The fall in membrane potential produced by the administration of 0.1 mM ouabain was greater than the effect of the redistribution of sodium potassium ions; this suggests that the sodium pump is functioning electrogenically, at least in part. The administration of 10 mM dinitrophenol, which caused a 74% fall in the ATP level in 15 min, also produced a depolarization that corresponded to stopping an electrogenic pump. A partial reduction in the level of ATP brought about by hypoxia, by 10 mM antimycin, or by 20 mM fructose resulted in a hyperpolarization that may be attributed to an elevation of potassium permeability (P_K), since it was concomitant to a loss of K from the liver. The change in membrane permeability was not related to a rise in the free calcium in the cells. The administration of 10 mM amobarbitone produced an immediate depolarization that was independent of the progressive reduction in the ATP level. The depolarization was attributed to a direct effect of amobarbitone that reduced the membrane permeability for potassium ions. The depolarization observed in ischemic anoxia was greater than that produced by ouabain for the same variation in ion concentrations. In addition to a likely inhibition of the electrogenic sodium pump, changes in membrane permeability inducing a rise in the P_{Na}/P_K ratio must also occur. After ischemic anoxia for 24 hr at 3 C, the ratio of P_{Na}/P_K rose to 0.68, which indicates that the selective character of membrane permeability was abolished. The augmentation in cell volume produced by anoxia might result in an opening of membrane pores, which could entail the augmentation of sodium permeability; the latter would be responsible in part for the depolarization produced by anoxia. According to the severity and length of oxygen deprivation an increase in P_K, a cessation of the sodium pump activity, and finally an increase in P_{Na} will occur.

8042 EFFECT OF ISCHAEMIA ON THE ENZYME ACTIVITY OF THE HEPATIC TISSUE.

(Eng.) Kupcsulik, P.; Stekker, K.; Nemeth, M. (Semmelweis Univ. Medical Sch., Budapest, Hungary). *Res. Exp. Med.* 170(3):259-270; 1977.

The lactate and pyruvate levels, as well as acid (AcP) and alkaline phosphatase (AlkP), lactate dehydrogenase (LDH), glucose-6-phosphate dehydrogenase (G6PD), glutaminic acid-oxalacetic acid transaminase (GOT), and aldolase levels of rat liver homogenates were measured at 24 C and 38 C during a 120-min ischemic period to determine whether the method is a sensitive indicator of ischemic lesions, whether the overall enzyme activity of the hepatic tissue or intracellular distribution of hepatic enzymes activities is the main susceptible indicator of ischemic lesions, and whether there is a time in the investigated ischemic period when typical, perhaps irreversible, changes could be detected. All the above-mentioned enzymes except GOT and aldolase were studied histochemically; microscopically visible enzyme-histochemical changes in hepatic tissue were also determined. During ischemia, the total lactate level rose significantly at 38 C ($p<0.001$-0.01), whereas the amount of membrane-bound lactate fell both at 24 C ($p<0.001$-0.01) and 38 C ($p<0.001$-0.01). The lactate to pyruvate ratio rose significantly after 100 min at 24 C ($p<0.01$) and was significantly higher at all time points at 38 C ($p<0.001$-0.01). The significant decrease in total aldolase activity at both 24 C ($p<0.001$-0.05) and 38 C ($p<0.001$-0.02) indicates a breakdown of aerobic glycolysis and the simultaneous start of lactic acid fermentation. The G6PD total activity increased simultaneously at both 24 C ($p<0.02$-0.05) and 38 C ($p<0.01$-0.02), pointing to the beginning of a pentose phosphate "shunt." During the later stages of ischemia, there were changes in AlkP, AcP, and LDH total activities, but these were not consistently significant and were more pronounced at 38 C than at 24 C. The membrane-bound activities of AlkP, AcP, and LDH all increased significantly ($p<0.001$-0.05) in the later stages of ischemia at both 24 C and 38 C. Fractionated study of the liver homogenate improved the assessability of enzyme determinations. However, no direct answer can be given to the time when irreversible lesions begin to develop. Quantitative testing of the liver homogenate and enzyme histochemical observation of the hepatic tissue might be a suitable method for the assessment of ischemic liver lesions.

8043 TREATMENT OF EXPERIMENTAL MURINE AMYLOIDOSIS WITH DIMETHYL SULFOXIDE. (Eng.) Kedar, I.; Greenwald, M.; Ravid, M. (Sackler Sch. Medicine, Tel Aviv Univ., Tel Aviv, Israel). *Eur. J. Clin. Invest.* 7(2):149-150; 1977.

The effect of dimethylsulfoxide (DMSO) on experimental amyloidosis was tested. DMSO (0.5 ml of 1.32 M/day) was administered i.v. for 60 days to 20 mice with casein-induced amyloidosis. Partial or total disappearance of amyloid deposits occurred in all treated animals. The urine of these animals contained a substance from which amyloid fibrils could be synthesized. A control group of mice with casein-induced amyloidosis that was given saline injections showed massive amyloid deposition in the liver and in the spleen at the end of the experiment. Neither the urine of these mice nor the urine of normal control mice treated with DMSO contained substances from which amyloid fibrils could be synthesized. The results indicate that DMSO treatment of mice with amyloidosis results in a breakup of amyloid fibers into small subunits that are excreted in the urine.

8044 A MICROPUNCTURE STUDY OF SALT AND WATER RETENTION IN CHRONIC EXPERIMENTAL CIRRHOSIS. (Eng.) Lopez-Novoa, J. M.; Rengel, M. A.; Rodicio, J. L.; Hernando, L. (Dept. Nephrology, Fundacion Jimenez Diaz, Madrid 3, Spain). *Am. J. Physiol.* 232(4):F315-F318; 1977.

The importance of increased sodium resorption in rats with chronic hepatic cirrhosis was studied using micropuncture techniques. Cirrhosis was induced by the administration of phenobarbital and carbon tetrachloride. The animals retained salt and water after loading and showed edema and ascites. Salt and water balance, clearance, and micropuncture tests were performed. Five or six weeks after the induction of liver injury, the rats were unable to excrete salt and water loads promptly. Urine flow and sodium concentration were significantly less in cirrhotic rats with edema and ascites than in the normal controls. The glomerular filtration rate was slightly lower in the right, nonmicropunctured kidney but was the same in the left. The nephron glomerular filtration rates of surface nephrons were equal in both the experimental and control rats. The fractional proximal resorption rate was notably greater in cirrhotic rats, as was the total proximal nephron resorption rate. It cannot be demonstrated from this study that increased proximal resorption alone might account for diminished sodium and water excretion. The authors believe that major evidence is provided of the importance of proximal resorption in this phenomenon.

8045 THE CIRCULATION IN LIVER TISSUE AND EXPERIMENTAL LIVER METASTASES BEFORE AND AFTER EMBOLIZATION OF THE LIVER ARTERY. (Eng.) Lindell, B.; Aronsen, K. F.; Rothman, U.; Sjogren, H. O. (Univ. Lund, Malmo General Hosp., S-21401 Malmo, Sweden). *Res. Exp. Med. (Berl.)* 171(1):63-70; 1977.

Simultaneous measurement of cardiac output (CO) distribution with ^{86}Rb- and ^{57}Co-tagged microspheres in rats implanted with sarcoma cell tumors (intraportal injection of sarcoma cells) enabled the quantitation of arterial and portal tumor circulation. Total liver circulation was reflected by the ^{86}Rb measurements, whereas the ^{57}Co-tagged spheres indicated arterial circulation to the liver. The portal circulation was taken as the difference between the total liver and arterial circulations. Portal circulation was increased in small tumors (0-2 mm) compared with that in the liver, with the CO fraction (%/g) being 0.66 ± 0.20 for liver tissue and 0.97 ± 0.30 for tumor tissue. However, portal circulation in medium- and large-sized tumors ($\geq$2 mm) was decreased compared with that in normal liver tissue (CO fraction values of 0.30 ± 0.14 and 0.81 ± 0.31, resp.). When tumor growth became massive, even the total liver circulation was reduced, as measured by a ^{133}Xe washout that showed a half-time of 44 ± 14 sec for livers with small and medium tumors and 102 ± 22.5 sec for livers with massive tumors. Xe washout was prolonged in livers with small and medium tumors when the liver artery was embolized by degradable microspheres. The preembolization half-time of 44 ± 14 sec was increased to 98 ± 43 sec. All liver tumors showed increased arterial circulation, with the ^{57}Co-sphere fraction (%/g) being 0.78 ± 0.65 for tumor tissue and 0.49 ± 0.22 for normal liver tissue. Arterial hyperperfusion was changed into ischemia when the liver artery was occluded through embolization with degradable microspheres.

8083 AMINO ACID METABOLISM OF DOG JEJUNUM BEFORE AND DURING ABSORPTION OF KETO ANALOGUES.

(Eng.) Weber, F. L., Jr.; Maddrey, W. C.; Walser, M. (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205). *Am. J. Physiol.* 232(3):E263-E269; 1977.

The proportion of keto analogues that disappear from the intestinal lumen and appear in the mesenteric venous blood as the unchanged keto acid or as its corresponding amino acid was determined. The keto analogues of the essential amino acids, leucine (L), valine (V), and isoleucine (IL), were infused into the lumen of the intact dog jejunum and the unchanged keto acids, the corresponding amino acids, or ammonium and urea were subsequently measured in mesenteric blood. Control experiments measured jejunal uptake and mesenteric vein release of 24 amino acids plus ammonium and urea. The keto analogues of L, V, and IL, infused for 1 hr at initial concentrations of 10 mM, disappeared from the lumen at a rate of 20.2 ± 1.6, 18.6 ± 2.0, and 15.7 ± 2.8 μmol/cm/hr, resp. Significant amination of keto analogues occurred in the gut wall since 8% of L, 15% of V, and 17% of IL keto analogues appeared as the corresponding amino acid in the mesenteric blood. The remainder of the absorbed keto analogues of V and IL appeared unchanged in the blood; however, 34% of the keto analogue of L did not appear and was probably catabolized by the gut wall. The results justify the oral administration of keto analogues of essential amino acids in patients with clinical disorders such as uremia and portal systemic encephalopathy where protein restriction is necessary.

8084 ACTIVATION AND RELEASE OF PROTEOLYTIC KININ-FORMING ENZYMES FROM RAT JEJUNAL LOOPS PERFUSED WITH HYPEROSMOLAR GLUCOSE SOLUTIONS.

(Eng.) Worthington, K. K.; Cuschieri, A. (Dept. Surgery, Liverpool Univ., Liverpool, England). *Gut* 18(4):279-283; 1977.

Loops of rat jejunum were perfused *in vivo* for 1 hr with de Jalon solutions (de Jalon 1, 259.6-de Jalon 4, 1,358.4 mOsm) of increasing glucose concentration (2.77-1,000 mM) to study the activation and release of proteolytic kinin-forming enzymes. The esterolytic activity of the perfusate and of the extracted loop was measured using benzoyl arginine ethyl ester as substrate. The enzymes LDH, isocitrate dehydrogenase, and acid phosphatase were measured in the perfusate to estimate the degree of cellular damage. There was a significant depletion of kallikrein from the intestine (De Jalon 2 perfused, 46.84 ± 23.29 ImU/ml; normal unperfused 98.90 ± 42.68 ImU/ml) and a raised level in the perfusate (28.01 ± 27.6 ImU/ml) during the hyperosmolar perfusions. However, no further increase in the release of proteolytic activity was found when the osmolarity of the perfusate was increased from 530 to 1,350 mOsm. The release of kallikrein into the perfusate was rapid, occurring in the first 20 min of the perfusion, whereas cellular damage as indicated by LDH (De Jalon 1 perfused, 57.04 ± 48.89 and De Jalon 4 perfused, 229.22 ± 175.32 ImU/ml) occurred only after 40 min of perfusion. Therefore, the effect of hyperosmolar solutions on the release of proteolytic enzymes is specific and may not be ascribed directly to cellular damage. It is concluded that hyperosmolar intestinal contents can act as a mechanism for the release of intestinal kinin-forming enzymes such as kallikrein into the circulation and suggest this mechanism is involved in the syndrome of vasomotor dumping after gastric surgery.

8085 INFLUENCE OF THE THYROID AND ADRENAL GLANDS ON THE GROWTH OF THE INTESTINE OF THE SUCKLING RAT, AND ON THE DEVELOPMENT OF INTESTINAL ALKALINE PHOSPHATASE AND DISACCHARIDASE ACTIVITIES.

(Eng.) Yeh, K. Y.; Moog, F. (Dept. Biology, Washington Univ., St. Louis, MO 63130). *J. Exp. Zool.* 200(3):337-348; 1977.

The stimulatory effects of thyroxine or cortisone treatments on the functional maturation of rat intestinal mucosa were studied in normal, thyroidectomized (6 days of age), and adrenalectomized (14 days) rats. The rats were given daily i.p. injections of either thyroxine (1 μg/g body weight) or cortisone acetate (50 μg/g) from 19 to 22 days and were sacrificed at 24 days. Thyroidectomized animals gained less body weight and small intestinal weight than controls by 24 days (32.9 ± 2.4 g versus 60.9 ± 2.6 g and 868 ± 38 mg versus 2.282 ± 140 mg total weight at 24 days, resp.); neither thyroxine nor cortisone therapy altered this result. The villi did not increase in height beyond the 6-day stage. Crypt depth in thyroidectomized animals (11.8 ± 0.5 cells), which was 64% of the control value (19.1 ± 0.4), was increased to 14.7 ± 0.4 and 14.2 ± 0.4 cells by cortisone and thyroxine, resp. ($p<0.001$ in both cases). The mitotic index was increased from 2.69 ± 0.16 to 3.44 ± 0.12% by thyroxine compared to a control value of 4.05 ± 0.13% ($p<0.001$ in both cases). Duodenal alkaline phosphatase was increased from 89 ± 6.8 μmol phenylphosphate (PhP)/mg protein/hr to 390 ± 31 and 612 ± 65 μmol PhP/mg/hr by cortisone and thyroxine, resp.; the latter was comparable to the control value of 502 ± 43 μmol ($p<0.05$) for all differences. Subnormal sucrase and maltase activities in thyroidectomized rats were more than doubled by both thyroxine and cortisone. Thyroxine and cortisone increased the carbohydrate content (PAS-staining material) in brush borders of thyroidectomized rats to normal levels. Body weight and small intestinal weight were lowered in adrenalectomized animals at 24 days than in control animals (46.5 ± 0.8 g and 1,432 ± 18 mg versus 59.0 ± 2.0 g and 2,353 ± 80 mg, resp); cortisone raised both body and intestinal weights (49.1 ± 1.6 g, $p>0.1$ and 1,820 ± 78, $p<0.001$), but thyroxine caused additional depressions. Cortisone increased villus height from 72.2 ± 1.7 to 81.6 ± 6.9 cells ($p<0.005$) and raised the mitotic index from 2.63 ± 0.10 to 3.30 ± 0.12% ($p<0.005$), whereas thyroxine was ineffective. Cortisone and thyroxine failed to increase subnormal crypt depths in adrenalectomized rats, but cortisone did increase the PAS-stainability of the brush borders. Duodenal alkaline phosphatase levels in adrenalectomized animals were increased to slightly greater than control values by both cortisone and thyroxine. Maltase activity was increased from 8.28 ± 0.57 to 19.49 ± 1.40 and 14.72 ± 1.13 μmol substrate/mg/hr by cortisone and thyroxine, resp., as compared to a control value of 21.60 ± 0.84 ($p<0.001$). Sucrase activity was increased from 1.56 ± 0.14 to 4.22 ± 0.31 and 2.33 ± 0.28 μmol substrate/mg/hr by cortisone and thyroxine, resp., as compared to a control value of 4.34 ± 0.31. Thyroxine was able to restore plasma adrenocorticosteroid levels to normal in thyroidectomized rats, but could not affect corticoid levels in hypophysectomized rats. These results demonstrate that the intestinal epithelium of the rat is able to respond to each hormone tested in the absence of the other.

8086 EFFECTS OF ANIONIC SURFACTANTS ON HAMSTER SMALL INTESTINAL MEMBRANE STRUCTURE AND FUNCTION: RELATIONSHIP TO SURFACE ACTIVITY. (Eng.) Gullikson, G. W.; Cline, W. S.; Lorenzsonn, V.; Benz, L.; Olsen, W. A.; Bass, P. (Sch. Pharmacy, 425 N. Charter St., Madison, WI 53706). *Gastroenterology* 73(3):501-511; 1977.

The relationship of the surface properties of a group of anionic surfactants to their effects on intestinal water transport was studied. Water transport was determined using everted hamster jejunal sacs. Dose-response inhibition of water transport (60-80% maximum inhibition, $p<0.05$) was obtained with two long-chain detergents (sodium dodecyl sulfate and dioctyl sodium sulfosuccinate), a fatty acid (ricinoleate), and dihydroxy bile salts (deoxycholate, chenodeoxycholate, and taurodeoxycholate), whereas no activity was seen with trihydroxy bile salts (cholate, glycocholate, and taurocholate, all at 8 mM) or a triketo bile salt (16 mM dehydrocholate). This effect on water transport paralleled the abilities of these compounds to lyse the erythrocyte, a membrane model. Both biological effects were related to the surface properties of the agents, as determined by critical micelle concentration and surface tension reduction. The effects of deoxycholate on the small intestine, *in vivo*, showed that alterations in intestinal permeability correlated with effects on fluid absorption. Concentrations of deoxycholate that induced secretion also increased ($p<0.05$) intestinal permeability to inulin, dextran, and albumin, and the rate of cell exfoliation. These changes were accompanied by both biochemical and histological alterations: exfoliation (DNA release), membrane effects (sucrase release), and shortened villi. Electron microscopy revealed extensive alteration ($p<0.005$) of the brush border membrane with a decrease in binding of lanthanum and the development of permeability to tracer in villus tip cells. Taurocholate (16 mM concentration), which did not alter water transport, also did not affect intestinal permeability or the brush border membrane. It is suggested that surface properties of anionic surfactants cause changes in absorptive cell membranes that result in intestinal secretion.

8087 INTESTINAL BRUSH BORDER ALKALINE PHOSPHATASE IN THE RAT AFTER PROXIMAL SMALL BOWEL RESECTION. (Eng.) Urban, E. (Audie Murphy Veterans Admin. Hosp., 7400 Merton Minter Blvd., San Antonio, TX 78284). *Proc. Soc. Exp. Biol. Med.* 155(1):99-104; 1977.

The effect of proximal small bowel resection on intestinal brush border alkaline phosphatase (AP) activity in the remaining duodenum, midgut, and ileum was studied in male albino Sprague-Dawley rats. Enzyme activity was measured 6-7 weeks after the rats were subjected to resection of 50 cm of the proximal intestine and anastomosis of remaining intestine or sham-operation. Studies of mucosal mass after resection revealed significant mucosal growth in the duodenum of the resected rats compared with controls (25.2 ± 1.5 mg/cm gut length versus 35.2 ± 3.6 mg/cm in controls and resected rats, resp.); similar results were found for the midgut (20.3 ± 2.2 mg/cm versus 28.7 ± 2.8 mg/cm in control and resected rats, resp.). In the duodenum, AP activity per gram of mucosa decreased, but the increased mucosal mass compensated for the loss so that total AP activity per cm of intestine did not change. In the midgut, AP activity, measured per gram of mucosa and per cm of intestine, increased. In the ileum, AP activity did not increase compared to sham-operated rats. Duodenal brush border alkaline phosphatase may be important for postresection transport adaptation.

8088 HARMALINE INTERACTION WITH SODIUM-BINDING SITES IN INTESTINAL BRUSH BORDER SUCRASE. (Eng.) Mahmood, A.; Alvarado, F. (Laboratoire de Physiologie Comparee, Universite de Paris-XI, Centre Universitaire d'Orsay, 91405 Orsay, France). *Biochim. Biophys. Acta* 483(2):367-374; 1977.

The effect of harmaline (3.3-12.8 mM) on Na^+-activated rabbit brush border sucrase was studied at pH 6.8. The reaction kinetics revealed harmaline to be a fully competitive inhibitor of the substrate, sucrose. It is hypothesized that harmaline (charged positively in the physiological pH range 5.2-9) might compete with an allosterically related sodium-binding site that has been postulated to be involved in the activation of sucrase by alkali metal ions. Because of its size, harmaline, when bound to the metal site, could at least partially overlap with the substrate site, thereby behaving as if it were an authentic, fully competitive inhibitor of the substrate. Alkali metals (Na^+, K^+, Li^+) can completely reverse the inhibition caused by harmaline, thereby further confirming the hypothesis.

8089 SUBCELLULAR DISTRIBUTION OF THIAMINE-PYROPHOSPHOKINASE AND THIAMINE-PYROPHOSPHATASE ACTIVITIES IN RAT ISOLATED ENTEROCYTES. (Eng.) Cusaro, G.; Rindi, G.; Sciorelli, G. (Istituto di Fisiologia umana dell'Universita, Via Forlanini 6, 27100 Pavia, Italy). *Int. J. Vitamin Nutr. Res.* 47(2):99-106; 1977.

The intracellular distribution of thiamine pyrophosphokinase (TPKase), which phosphorylates thiamine, and of thiamine pyrophosphate (TPPase), which dephosphorylates thiamine pyrophosphate, was studied in rat enterocytes. Cellular fractionation was carried out in isolated small intestinal cells. TPKase activity was localized mainly (96-98%) in the supernatant fraction, and only minor amounts were found in mitochondria and microsomes. TPPase activity was present only in the particulate fractions (especially in the microsomes). The fact that TPKase is localized in the cytosol indicates that this enzyme probably does not play a role as a carrier for active intestinal transport of thiamine.

8090 GLYCOPROTEIN SYNTHESIS, TRANSPORT, AND SECRETION BY EPITHELIAL CELLS OF HUMAN RECTAL MUCOSA: NORMAL AND CYSTIC FIBROSIS. (Eng.) Neutra, M. R.; Grand, R. J.; Trier, J. S. (Harvard Medical Sch., 25 Shattuck St., Boston, MA 02115). *Lab. Invest.* 36(5):535-546; 1977.

The synthesis, transport, and secretion of glycoprotein by rectal epithelium from four normal volunteers, six patients with cystic fibrosis, and six of their disease-free siblings were studied by autoradiography of rectal biopsies pulse-labeled with ^{3}H-glucosamine and maintained in organ culture for various intervals of up to 24 hr. Within any one biopsy sample, the movement of labeled mucus in goblet cells varied widely among cells. Even with individual cells, labeled mucous granules often did not move in concert toward the apical cell surface. The average transport time in the cells of the cystic fibrosis patients and their siblings did not differ significantly from those of the adult controls. The carbohydrate composition of glycoprotein secretions of rectal epithelial cells was investigated by comparing autoradiographs of ^{3}H-glucosamine-labeled biopsies with those labeled with ^{3}H-fucose, ^{3}H-*N*-acetylmannosamine, and ^{35}S-sulfate. The patterns of incorporation of these four precursors into normal goblet and columnar cells suggested that both cell types may alter the quantity and composition of newly synthesized glycoproteins as they migrate, mature, and senesce. Incorporation patterns in cystic fibrosis biopsies were indistinguishable from those of sibling or adult controls. With the techniques used, no abnormalities of epithelial glycoprotein production were detected in cystic fibrosis rectal mucosa.

8091 MORPHOMETRIC AND AUTORADIOGRAPHIC INVESTIGATION OF THE SMALL AND LARGE INTESTINAL MUCOSA OF RATS WITH CHRONIC EXPERIMENTAL RENAL INSUFFICIENCY. (Eng.) Lohrs, U.; Arnholdt, H. (Pathologisches Institut der Universitat Munchen, Thalkirchner Strasse 36, D-8000 Munchen 2, W. Germany). *Beitr. Pathol.* 159(4):325-342; 1976.

The changes of the small and large intestinal mucosa of rats with surgically induced chronic renal insufficiency were analyzed. The rate of the physiological cell regeneration was inhibited in renal insufficiency, and this was correlated with the degree of insufficiency. The generation time was extended up to 40% in the ileum and up to 50% in the large intestine in the animals with the highest degree of renal insufficiency. This extension was mainly due to a prolongation of the postmitotic G$_1$-phase. At the same time, the total number of crypt epithelia and regenerative cells in the enlarged crypts increased. The enlargement of the regenerative crypt population is interpreted to be an adaptive compensation of the inhibition of the cell production by prolongation of the mitotic cycle. Differentiated surface epithelial cell damage was not detected. The results of this study, as well as those of previous studies, suggest the following hypothesis for the development of uremic enterocolitis: an initial decrease in the cell production rate occurs as a result of a prolonged mitotic cycle in renal insufficiency. When this decrease is not compensated for by an increase in the number of regenerative cells, as after uremic toxemia of sudden onset, erosive or ulcerative mucosal changes or simple mucosal atrophy will occur.

8092 ASSESSMENT OF THE SPECIFICITY OF ENZYMATIC REACTIONS USING MIXED SUBSTRATES: INCORPORATION OF ALKYLGLYCEROLS IN THE IONIC ALKOXYLIPIDS OF THE RAT'S INTESTINAL MUCOSA. (Eng.) GENERAL

8099 HYPERSENSITIVITY REACTIONS IN THE SMALL INTESTINE. III. THE EFFECTS OF ALLOGRAFT REJECTION AND OF GRAFT-VERSUS-HOST DISEASE ON EPITHELIAL CELL KINETICS. (Eng.) MacDonald, T. T.; Ferguson, A. (Univ. Glasgow, Dept. Bacteriology and Immunology, Glasgow, Scotland). *Cell Tissue Kinet.* 10(4):301-312; 1977.

Allograft rejection of fetal intestine and graft-versus-host (GvH) disease were used to study the effects of cell-mediated immune reactions on epithelial cell kinetics in the mouse small intestine. In heterotopically transplanted isografts, the cell production rate per crypt was similar to that in normally sited small intestine of the same age. However, there was a sixfold increase in the rate of cell production per crypt during allograft rejection and a threefold increase during GvH disease. Animals with GvH disease developed villus atrophy and had fewer crypts per villus than littermate controls. At the age of 19 days, cell production was 97.5 cells/villus/hr in animals with GvH disease, compared with 54.6 cells/villus/hr in controls. These results indicate that the pathological entity of "partial villus atrophy" evolves in two distinct phases. Phase 1, a state of increased cell turnover with crypt hyperplasia but villi of normal length, precedes the development of phase 2, true villus atrophy.

8100 INTESTINAL STIMULATION OF THE SERUM ANTIBODY RESPONSE AGAINST Escherichia coli O83 ANTIGEN IN HEALTHY ADULTS. (Eng.) Jodal, U.; Ahlstedt, S.; Hanson, L. A.; Lidin-Janson, G.; Akerlund, A. S. (Inst. Medical Microbiology, Guldhedsgatan 10, S-413 46 Goteborg, Sweden). *Int. Arch. Allergy Appl. Immunol.* 53(6):481-489; 1977.

The levels and avidities of *Escherichia coli* O83 antibodies were studied after colonization experiments in 11 healthy subjects. The ingestion of *E. coli* O83 bacteria preceded by 2 g of $NaHCO_3$ resulted in the bacteria appearing as a transient strain in the stool in 6 of the 11 subjects. No rise in serum, urine, or parotid fluid antibody levels against the crude O antigen from *E. coli* O83 bacteria was detected using the enzyme-linked immunosorbent assay (ELISA) or the indirect hemagglutination (IHA) technique. In contrast, a serum antibody response was registered in four subjects with the ammonium sulfate precipitation (ASP) technique. The rise in antibody level was accompanied by an increase in relative average antibody avidity. Significantly lower levels of serum antibodies against the *E. coli* O83 and O6 antigens were recorded using the ASP technique, as compared with those for O2, O4, and O75 antigens. The results indicate that determinations of serum antibody levels with the ELISA and the IHA techniques are not affected by minor changes in the intestinal bacterial flora and should therefore be used for diagnostic purposes.

8101 EFFECT OF INTRALUMINAL OXYGEN ON ENDOTOXIN ABSORPTION IN EXPERIMENTAL OCCLUSION OF THE SUPERIOR MESENTERIC ARTERY. (Eng.) Shute, K. (St. Thomas' Hosp., London, England). *Gut* 18(7): 567-570; 1977.

The effect of intraluminal oxygen administration during ischemia on the absorption of bacterial endotoxin after release of an experimental occlusion of the superior mesenteric artery (SMA) was studied in male Wistar rats. The presence and level of endotoxin in the rat plasma was assayed by determining the mortality rate following injection of plasma with and without 12.5 μg of actinomycin D i.p. into Swiss mice (the drug enhances the lethal effect of endotoxin by up to 225,000 times). Seven percent of mice injected with rat plasma taken after SMA without oxygen occlusion died. Sixty-five percent of those mice injected with this plasma and actinomycin D were dead at 48 hr. The mortality in this group was significantly higher than the mortality of those mice given this plasma alone ($p<0.001$) or of mice given control plasma (no occlusion or oxygen) and actinomycin D ($p<0.001$). Fifty-five percent of mice given actinomycin D and this plasma heated to 70 C died. Seventy percent of those given autoclaved plasma and actinomycin died. The mortalities in these two groups were not significantly different from the mortality of mice given unheated post-SMA occlusion plasma and actinomycin D. However, only 23% of mice given actinomycin D and post-SMA occlusion plasma from oxygen-treated rats died. This latter mortality is significantly lower than the 65% mortality of mice given actinomycin D and plasma from untreated rats ($p<0.001$). The results indicate that intraluminal oxygen during ischemia somehow decreases the amount of endotoxin absorbed into the superior mesenteric vein blood following the release of the SMA occlusion.

8102 RESISTANCE OF GERMFREE RATS TO INDOMETHACIN-INDUCED INTESTINAL LESIONS. (Eng.)

Robert, A.; Asano, T. (Dept. Experimental Biology, Upjohn Co., Kalamazoo, MI 49001). *Prostaglandins* 14(2):333-341; 1977.

The effect of indomethacin on the development of intestinal lesions was studied in germfree (gnotobiotic) rats and in gnotobiotic rats monocontaminated with *Escherichia coli*, and the protective effect of prostaglandins was investigated. Indomethacin (10 and 20 mg/kg) given p.o. to conventional rats produced a syndrome of intestinal lesions characterized by multiple ulcers and peritonitis within 3 days. Male germfree rats were found to be resistant to this effect of indomethacin, while female germfree rats developed very mild lesions. Germfree rats became sensitive again to such lesions when monocontaminated with *E. coli*. In such animals, however, the lesions were less severe than in conventional animals, presumably because more than one microorganism is necessary for the full syndrome to develop. These results suggest that microorganisms are necessary for the development of indomethacin-induced intestinal lesions. Secondary bile acids, absent in germfree animals, may also be necessary. The prostaglandin deficiency caused by indomethacin appears to weaken the resistance of the intestinal mucosa to microorganisms and/or their toxins. The latter may then penetrate the mucosa, damage the cells, and produce ulcers and perforations. Since 16,16-dimethyl prostaglandin E_2 (0.3 mg/kg, twice daily for 3 days, p.o.) protected against indomethacin-induced lesions, it is hypothesized that certain prostaglandins may protect the mucosa by preventing the spread of microorganisms and/or their toxin through the intestinal wall.

8103 PROMOTING EFFECT OF BILE ACIDS IN COLON CARCINOGENESIS IN GERM-FREE AND CONVENTIONAL F344 RATS. (Eng.)

Reddy, B. S.; Watanabe, K.; Weisburger, J. H.; Wynder, E. L. (Naylor Dana Inst. for Disease Prevention, American Health Foundation, Valhalla, NY 10595). *Cancer Res.* 37(9): 3238-3242; 1977.

The promoting effect of sodium cholate or sodium chenodeoxycholate on colon carcinogenesis was studied in female F344 germ-free and conventional rats. Both germ-free and conventional rats received intrarectal instillations of *N*-methyl-*N*'-nitro-*N*-nitrosoguanidine (MNNG) for 2 weeks (total dose, 8 mg) and then intrarectal doses of sodium cholate or sodium chenodeoxycholate (20 mg/dose) 3 times a week for 46 weeks; other groups received MNNG for 2 weeks and vehicle thereafter for 46 weeks or bile acids alone for 48 weeks. Sodium cholate or sodium chenodeoxycholate increased MNNG-induced adenocarcinomas and adenomas in germ-free rats, whereas in conventional rats these bile acids induced more adenomas. Conventional rats treated with MNNG plus sodium cholate or MNNG plus sodium chenodeoxycholate had a higher incidence ($p<0.05$) of colon tumors than did those given MNNG alone; germ-free rats that received MNNG plus sodium cholate or MNNG plus sodium chenodeoxycholate had a higher but not significant ($p>0.05$) frequency of colon tumors than did those given MNNG alone. No tumors were detected in the colons of germ-free and conventional rats given sodium cholate or sodium chenodeoxycholate alone. It is concluded that sodium cholate and sodium chenodeoxycholate have a promoting effect in MNNG-induced colon carcinogenesis in rats.

8104 MECHANISMS UNDERLYING GASTRIC MUCOSAL DAMAGE INDUCED BY INDOMETHACIN AND BILE-SALTS, AND THE ACTIONS OF PROSTAGLANDINS. (Eng.)

Whittle, B. J. R. (Wellcome Res. Lab., Langley Court, Beckenham, Kent BR3 3BS, England). *Br. J. Pharmacol.* 60(3):455-460; 1977.

The mechanisms by which sodium taurocholate potentiates the formation of gastric mucosal erosions induced by indomethacin was investigated in the rat. Systemic administration of indomethacin (10-20 mg/ml) lowered resting mucosal blood flow but had no effect on the acid back-diffusion across the mucosa. Gastric perfusion of taurocholate in acid solution increased acid back-diffusion and lowered the potential difference. This was accompanied by an increase in mucosal blood flow, which may represent a protective mechanism in the mucosa. The administration of indomethacin during 2 mM acid-taurocholate perfusion reduced this elevated mucosal blood flow without any further change in acid back-diffusion. The results suggest that although a decrease in mucosal blood flow or an increase in acid back-diffusion can lead to a low incidence of erosions; a combination of both produces extensive mucosal damage. The (15S)-methyl analogue of prostaglandin E_2 (5 μg/kg/hr) reduced erosion formation induced by 20 mg/kg indomethacin and 2 mM acid-taurocholate administration. This protective action of the prostaglandin analogue may be linked to changes in gastric mucosal permeability and in mucosal blood flow.

8105 ROLE OF INTRAGASTRIC PRESSURE, pH, AND PEPSIN IN GASTRIC ULCERATION IN THE RAT.

(Eng.) Alphin, R. S.; Vokac, V. A.; Gregory, R. L.; Bolton, P. M.; Tawes, J. W., III. (A. H. Robins Res. Lab., 1211 Sherwood Ave., Richmond, VA 23220). *Gastroenterology* 73(3):495-500; 1977.

The development of experimental gastric ulcers in the rat was studied by a method of continuous gastric perfusion with artificial gastric juice to evaluate the contribution of pH, pepsin, and intragastric pressure on the pathogenesis of peptic ulcers. This method allowed the change of only one factor at a time, while the other two remained constant. The gastric mucosa of normal, 48-hr fasted rats was resistant to the ulcerogenic effects of artificial gastric juice perfused through the stomach for 6 hr without an increase in intragastric pressure (2.5 cm water). Perfusion of HCl (pH 1.3) under increasing pressure (5-12.5 cm water) produced ulceration of the corpus as well as the forestomach portion of the stomach (ulcer index 126 ± 34 at a pressure of 12.5 cm). The addition of porcine pepsin to the perfusate at a pressure of 7.5 cm water increased the incidence and severity of ulceration ($p<0.05$). The degree of gastric ulceration paralleled increases in intragastric pressure, acidity, and pepsin proteolytic activity. Inhibition of pepsin activity by a pepsin inhibitor (sodium lignosulfonate, 2.5-5.0 mg/min) protected the gastric mucosa, even at a pH of 1.3. These results demonstrate that under the experimental conditions used, HCl alone, in the absence of pepsin, does not produce ulceration of the rat stomach.

8106 GASTRIC ULCERATION ASSOCIATED WITH EXPERIMENTAL VASCULAR OCCLUSION. (Eng.)

Svanes, K.; Ulven, A. (Haukeland sykehus, Bergen, Norway). *Digestion* 15(6):517-525; 1977.

To investigate the significance of the different vascular beds of the stomach wall in the development and healing of gastric ulcers, vascular occlusion was induced in the glandular layer or in the submucosa of the cat stomach. The left gastric artery was cannulated in 17 cats, and a single dose of microspheres was injected into the artery, after which it was ligated. Microspheres with diameters of 8-10 μm induced gastric mucosal erosions that healed within 1-2 weeks. Microscopic examination revealed that there were few microspheres in the submucosa, more in the muscularis, and large numbers in the glandular layer. The muscularis mucosae was intact. After the injection of 50 ± 5 μm spheres, a large gastric ulcer developed. The ulcers healed after 4 weeks. Microscopically, the ulcer penetrated through the muscularis mucosae, and many microspheres were seen in the submucosa and serosa beneath the ulcer. The results suggest that slow healing of a gastric ulcer may be due, at least in part, to vascular occlusion in the submucosa.

8107 ESTIMATION OF THE HEPATIC BLOOD FLOW IN THE DOG WITH THE Xe^{133} AND HYDROGEN WASHOUT, Au^{198}-COLLOID UPTAKE TECHNIQUES AND WITH THE ELECTROMAGNETIC FLOWMETER. (Eng.)

Szabo, G.; Benyo, I.; Sandor, J.; Benyo, Z. (Semmelweis Univ. Medical Sch., Budapest, Hungary). *Res. Exp. Med. (Berl.)* 169(1):69-76; 1976.

To estimate hepatic blood flow, electromagnetic flow meter probes were positioned around the isolated common hepatic artery (CHA) and the portal vein (PV) of 15 anesthetized dogs weighing between 15 and 21 kg. A fluorocarbon catheter was introduced into the PV, two Pt needle electrodes were inserted 3 mm deep into the right and left hepatic lobes, and a reference probe was inserted subcutaneously into the thigh. A collimated NaI scintillation detector was placed 20 cm above the liver giving a visual field of from 1/3 to 1/2 of the anterior hepatic surface. For radiogold clearance, the detector was positioned directly over the animal's skull. Femoral artery and PV pressures were measured with Statham strain gauges. Hydrogen gas was introduced via intratracheal tube, ^{133}Xe gas in saline was injected into the mesenteric branch, and radioactive colloidal gold (^{198}Au) in dextran was injected into the femoral vein. Total hepatic blood flow (HBF) averaged 142 ± 10.4 ml/min/100 g. Nonhepatic flow was found to be 23.5% of the hepatic artery flow. Since the CHA flow rate is 30.3% of the combined flow, HBF estimations are exaggerated by approximately 7%. Inert gas measurements yielded considerably lower values for HBF than the direct method. There was good correlation between results obtained with the ^{198}Au colloid clearance method and the simultaneous combined flowmeter method ($r=0.830$, $p<0.01$); the HBF was 153 ± 13 ml/min/100 g by the former method and this was 96.5 ± 5.0% of the value by the latter method. Considering that the combined flowmeter readings are approximately 7% higher than the true HBF, ^{198}Au colloid HBF is essentially the same as the average value obtained by direct measurement. HBF estimated with the colloidal gold uptake technique showed the best agreement with the direct measurements; the technique has numerous advantages, its only drawback being the high radioactivity required in a single determination that represents a hazard to the investigator carrying out serial determinations.

8108 THE EFFECT OF TRUNCAL VAGOTOMY ON TAUROCHOLATE CHOLERESIS AND SECRETIN CHOLERESIS. (Eng.)

Jones, R. S.; Smith, B. M. (Duke Univ. Medical Center, Durham, NC 27710). *J. Surg. Res.* 23(3):149-154; 1977.

The effect of truncal vagotomy on bile secretory processes was investigated in dogs. The animals underwent cholecystectomy, chronic bile and gastric fistulas, and pyloroplasty. Taurocholate choleresis and secretin choleresis were observed before and after truncal vagotomy. Vagotomy caused minor decreases in bicarbonate output and an increase in chloride output but had no influence on bile flow, bile salt concentrations, or bile salt output. Vagotomy had no influence on secretin choleresis. The findings indicate that previously observed reductions in bile salt secretion after vagotomy are due to some mechanism other than the influence of vagotomy on hepatic bile secretion.

DIAGNOSTIC PROCEDURES

8123 GRAY SCALE CHOLECYSTOSONOGRAPHY: DIAGNOSTIC CRITERIA AND ACCURACY. (Eng.) Lawson, T. L. (George Washington Univ. Medical Center, Washington, DC 20037). *Radiology* 122(1): 247-251; 1976.

Preoperative fasting cholecystosonography scans were performed on 81 patients with cholecystitis symptoms and an abnormal oral cholecystogram. Ultrasonograms were compared with oral cholecystograms and surgical findings, and gallbladder diameter was measured in 51/81 patients with confirmed disease. Evidence of cholecystitis and/or cholelithiasis was found in 80/81 patients. Of all patients referred for pancreatic ultrasonography, 15 had extrahepatic biliary obstruction, 10 had pancreatic carcinoma, 2 had cholangiocarcinoma of the hepatic and common hepatic bile ducts, 2 had pancreatic metastases, and 1 had enlarged lymph nodes in the pancreatic region secondary to lymphoma. Positive diagnosis of cholelithiasis was made in 56/81 patients on the basis of internal echos, organ wall irregularities, and sonic shadows, singly or in combination. Overall diagnostic error was approximately 5%. Three false-negative diagnoses of cholelithiasis were probably due to poor technique, since stones were eventually found to be 1-3 cm in diameter. There was good correlation between cholecystosonograms and oral cholecystograms in 47 patients for whom data were available. Small single stones (7 mm) and aggregates (<7 mm) were visualized in several patients. Cholecystosonograph measurements of the gallbladder in patients with confirmed extrahepatic biliary obstruction correlated well with size found at surgery, but the use of this parameter in the diagnosis of chronic cholecystitis or extrahepatic biliary obstruction is thought to be tenuous. When dilated intrahepatic bile ducts are demonstrated, a diagnosis of extrahepatic biliary obstruction may be made.

8124 ACCURACY OF COMPUTED TOMOGRAPHY OF THE LIVER AND BILIARY TRACT. (Eng.) Levitt, R. G.; Sagel, S. S.; Stanley, R. J.; Jost, R. G. (Mallinckrodt Inst. Radiology, Washington Univ. Sch. Medicine, 150 S. Kingshighway, St. Louis, MO 63110). *Radiology* 124(1):123-128; 1977.

The accuracy of computed tomography (CT) scanning of the liver and biliary tract was investigated in 266 patients. The identification of 43 of 46 proved cases of space-occupying lesions within the liver was accomplished with CT, and in 36 cases the nature of the lesion was clarified by CT. Technical errors in the measurement of the attenuation value of the lesions were responsible for 3 of 10 erroneous diagnoses. When attenuation values fall into the overlapping range of cysts and abscesses (10-20 Hounsfield U [HU]) or of abscesses and tumors (20-30 HU less than the normal liver parenchyma), CT cannot clarify the nature of the lesion. Values for lesions smaller than 2 cm will be erroneously high or low due to partial volume averaging. Obstructive jaundice was correctly identified in 38 of 39 proved cases, and nonobstructive jaundice in 21 of 26 proved cases. In obstructive jaundice, the site or cause of the obstruction was defined by CT scanning in 30 of 39 cases. Hepatocellular disease (e.g., cirrhosis) was less accurately detected by CT, with only 10 of 22 cases in the above series being recognized.

GASTROINTESTINAL DISEASES

ESOPHAGUS

8146 GASTRIC ACID SECRETION IN PATIENTS WITH SYMPTOMATIC HIATUS HERNIA AND EFFECT OF A MODIFIED BELSEY MK IV REPAIR ON GASTRIC ACID SECRETION. (Eng.) Boesby, S. (Odense Univ. Hosp., Odense, Denmark). *Scand. J. Gastroenterol.* 12(4): 401-406; 1977.

Fasting, basal, and maximal (pentagastrin-stimulated) gastric acid secretion was assessed in 53 patients with radiologically verified sliding hiatal hernia without esophageal stricture. The mean values for fasting total acid (H^+) secretion, basal acid output, and peak acid output were 0.5 mEq H^+ (range, 0-2.8), 1.7 mEq H^+/hr (range, 0.01-6.3), and 23.92 mEq H^+/hr (range, 0-55.96), resp. There were no significant differences between patients with heartburn and those with heartburn and pain in terms of pH, volume, acidity, and acid output for fasting and basal acid secretions or in terms of peak acid output and volume for maximal acid secretion. A study of another 34 patients before and 3 months after a modified Belsey MK IV repair for symptomatic hiatal hernia revealed that after the repair, the mean pH of basal secretion had risen significantly ($p<0.01$) from 2.8 (range, 1.3-8.2) to 3.8 (range, 1.4-7.6), the mean volume of basal secretion had fallen significantly ($p<0.01$) from 44.0 ml (range, 2-140) to 30.0 ml (range, 2-66), the mean basal acid output had fallen significantly ($p<0.05$) from 1.9 mEq H^+/hr (range, 0.2-4.7) to 1.2 mEq H^+/hr (range, 0.04-2.93), the mean peak acid output had fallen significantly ($p<0.001$) from 22.7 mEq H^+/hr (range, 0-55.96) to 17.2 mEq H^+/hr (range, 0-49.2), and the mean volume of maximal acid secretion had fallen significantly ($p<0.001$) from 189.0 ml/hr (range, 51-384) to 145.0 ml/hr (range, 23-318). These changes are probably due to an unintentional vagotomy during the operation. Changes in gastric acid secretion should be considered in the evaluation of a surgically established barrier against gastroesophageal reflux in terms of esophageal pH.

8147 ESOPHAGEAL INTRAMURAL PSEUDODIVERTICULOSIS. (Eng.) Fromkes, J.; Thomas, F. B.; Mekhjian, H.; Caldwell, J. H.; Johnson, J. C. (Ohio State Univ. Hosp., 410 West Tenth Ave., Columbus, OH 43210). *Am. J. Dig. Dis.* 22(8):690-700; 1977.

Three cases of esophageal intramural pseudodiverticulosis (EIP) are reported, and another 22 cases from the literature are reviewed. The classic radiographic picture of EIP, which is that of collar-button-shaped outpouchings projecting in a perpendicular fashion from the luminal surface, appears to be mainly related to dilatation in the esophageal glandular ductal system. In one of the cases reported, where outpouchings were found only in the distal esophagus, histologic evidence of severe esophagitis and manometrically demonstrated aperistalsis were seen throughout the entire body of the esophagus. These observations, combined with the fact that in several cases the outpouchings developed in radiographically normal esophagi, support the theory that the inflammatory process precedes structural dilatation. The disease is usually diagnosed (56% of cases) in the sixth and seventh decades of life, although all ages may be affected. Dysphagia is a very common (84%), but not universal, symptom of the disease process. The only disease significantly associated with EIP is diabetes mellitus, which is present in 32% of such patients. Strictures of the esophagus are frequently seen (60%), and varying degrees of esophagitis are manifested endoscopically in about 50% of the cases. Esophageal motility disturbances are common (77%) and may be severe. *Candida albicans* was cultured from the esophagus in 24% of the cases, and biopsies revealed evidence of tissue invasion in 8% of these cases. It is concluded that EIP is an inflammatory disease of unknown etiology characterized by dilatation of the esophageal submucosal glandular elements.

8148 THE DEADLIEST RUPTURE: IDIOPATHIC MUSCULAR HYPERTROPHY OF THE ESOPHAGUS. (Eng.) Penka, W. E.; Edwards, W. D.; Preskorn, S. H.; Kepes, J. J. (KUMC, Coll. Health Sciences and Hosp., 39th and Rainbow Blvd., Kansas City, KS 66103). *J. Kans. Med. Soc.* 78(6):269-275; 1977.

Five cases of idiopathic muscular hypertrophy of the esophagus are presented, two of which were complicated by esophageal rupture. Antemortem diagnosis of the disorder was not established in any of the patients, although diffuse esophageal spasm and a hypertonic lower esophageal sphincter were noted in one. Gastroesophageal symptoms were present in three of five patients. The hypertrophy involved the esophagus diffusely in two patients and was limited to the distal esophagus in three. The esophageal wall thickness varied from 0.4 to 1.0 cm. Preferential hypertrophy of the esophageal inner circular muscle was noted in three patients, but both the inner circular and outer longitudinal muscles were hypertrophied in the other two. Lymphocytic inflammation involved the ganglia of Auerbach's plexus in all patients. Marked eosinophilic inflammation of the hypertrophied circular muscle layer was present in two. In all patients, both the muscular hypertrophy and the inflammation of Auerbach's plexus ended abruptly at the cardioesophageal junction, and they were not present elsewhere in the gastrointestinal tract. Two of the five cases were complicated by linear transmural tears of the left posterolateral wall of the distal supradiaphragmatic esophagus (Boerhaave's syndrome); fulminant mediastinitis resulted, and it led directly to the deaths of the patients.

STOMACH

8162 GASTRIC SECRETORY AND MOTILITY STUDIES IN CHRONIC CHAGASIC PATIENTS. (Eng.) Padovan, W.; Meneghelli, U. G.; De Godoy, R. A. (Hospital das Clinicas, 14 100 Ribeirao Preto, Sao Paulo, Brazil). *Am. J. Dig. Dis.* 22(7):618-622; 1977.

Electromanometric and secretory studies were performed in 22 patients with Chagas' disease and in 12 control subjects. Gastric antrum electromanometric recordings were made under basal conditions and during stimulation with methacholine chloride (0.05 mg/kg, s.c.). Gastric secretory studies were performed with a Kay's test alone and with an augmented histamine test involving the s.c. administration of five doses of bethanechol chloride (0.025 mg/kg each). Signs of parasympathetic involvement of the stomach were exhibited by 10 of the chagasic patients. Patients were divided into two groups with respect to normal (group I) or abnormal (group II) gastric motility patterns. The mean of the maximal acid output (MAO) of each of the chagasic groups was significantly lower than that of the control group ($p<0.005$). Under the additional action of bethanechol, the MAO of control subjects did not change, but the MAO for chagasic patients increased by about 65%. As a result, the MAO of group I chagasic patients showed no significant difference from that of the control group, but the mean MAO for group II patients, although increased by the action of bethanechol, was still significantly lower than that of the control group ($p<0.005$). The mean maximal pepsin output (MPO) of each chagasic group was also significantly lower than that of the control group ($p<0.005$). Under the additional action of bethanechol, the MPO of controls and of group II patients did not change significantly; the MPO of group II patients was still significantly lower than that of controls ($p<0.005$), however, the MPO of group I patients doubled and approximated the control value. It is concluded that the parasympathetic denervation in Chagas' disease changes both acid and pepsin secretions in the same direction but, as the disease worsens, the responsiveness of pepsin secretion to cholinergic action tends to disappear earlier than that of acid secretion.

8163 PNEUMATOSIS CYSTOIDES INTESTINALIS: A CASE STUDY USING TRANSMISSION AND SCANNING ELECTRON MICROSCOPY. (Spa.) Llombart Bosch, A.; Lujan Pujante, E.; Forteza Villa, J.; Gomez Fayren, J. M. (Facultad de Medicina de Murcia, Murcia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47 (5):611-634; 1976.

A 70-yr-old man treated for inguinal and stomach hernias experienced periods of epigastric pain for 20 yr. Surgical intervention after radiological examination revealed pyloric stenosis and pyloroduodenitis with intense perivisceritis; a 2/3 gastrectomy was performed. At this time, pneumatosis cystoides intestinalis (PCI) was discovered on a 50-cm segment of the small intestine (terminal ileus) and was totally resected. The patient recovered and remains well 1.5 years after surgery. The resected PCI segment contained very small gaseous cysts (0.1-0.3 cm diameter), both isolated and confluent, arranged in linear or circular fashion and covered by a fine membrane. The histological characteristics are described for the granulomatous structures, gaseous cysts, the intestinal wall, and gastric ulcer. Fine structure is described for granular tissue, bullae, and the intestinal wall; a scanning electron microscope was used to study the same tissues, concentrating on the subserous and submucosal areas of the cystic walls.

8164 OBSERVATIONS ON THE GASTRIC MUCOSA OF RHEUMATIC PATIENTS BEFORE AND AFTER IBUPROFEN ADMINISTRATION AS STUDIED BY THE PENTAGASTRIN TEST, ENDOSCOPY, AND LIGHT AND ELECTRON MICROSCOPY. (Eng.) Vasconcelos Teixeira, A.; Abrunhosa, R.; Pocas, L. (Hosp. S Joao, Oporto, Portugal). *J. Int. Med. Res.* 5(4):243-252; 1977.

The effect of ibuprofen on the gastric mucosa in the rheumatic patients was studied in seven male patients aged 17-70 yr suffering from various rheumatic diseases. All patients received a daily dose of 1,200 mg of ibuprofen p.o. in three fractions over treatment periods ranging from 1 to 6 weeks. The values for acid secretion did not change in any patient after ibuprofen treatment. No patient exhibited any morphological alteration attributable to ibuprofen. The nucleus, mitochondria, and plasma membranes seemed unaffected by the drug treatment. In three patients, giant vacuoles were observed in the cytoplasm of the antral mucosa only in specimens obtained after ibuprofen treatment. These vacuoles were located in the immediate vicinity of the basal pole of the nucleus, occurred singly or apparently comprising a pair, were bounded by their own trilaminar membrane, and were surrounded by a layer of rough, dense cytoplasm. In their proximity, it was possible to observe much enlarged cisternae of rugose endoplasmic reticulum. Further investigation is suggested to determine the true nature of these vacuoles. It is concluded that, in the cases investigated, ibuprofen was not responsible for significant modifications of the gastric mucosa.

8165 THE MORPHOLOGY OF THE ANTRUM AND PYLORUS IN GASTRIC ULCER DISEASE. (Eng.) Liebermann-Meffert, D.; Allgower, M. (Kantonspital, CH-4031 Basel, Switzerland). *Prog. Surg.* 15:109-139; 1977.

To investigate the morphology of the antrum and pylorus in gastric ulcer disease, the terminal antrum and pylorus from 77 patients was examined at the time of surgery, and their appearances were compared with 50 control specimens. The thickness of the antropyloric wall was measured at the pylorus and in the antrum, 2.5 and 5 cm proximal to the pylorus. The increase in thickness was chiefly due to the muscle layer, but the submucosa and mucosa were also involved. The muscle hypertrophy was mostly irregular and involved different parts of the pylorus and antrum to a variable degree. Histological abnormalities of the antropyloric wall in gastric ulcer included hypertrophy of the muscle nuclei with areas where muscle fibers showed vacuolation, degeneration, and occasionally necrosis. The ganglia in these areas were reduced in number and also showed abnormal features. Mast cell and eosinophilic infiltration and areas of fibrosis and changes on the blood vessels were present. Most specimens with gastric ulcer showed severe gastritis with submucosal edema. The findings indicate that gastric ulcer is commonly associated with hypertrophy of the antropyloric wall and severe gastritis.

Peptic Ulcers

8180 RELATIONSHIP BETWEEN UNDISSOCIATED ACIDITY OF GASTRIC JUICE AND GASTRIC PROTEIN SECRETED IN RESPONSE TO GRADED DOSES OF PENTAGASTRIN IN DUODENAL ULCER PATIENTS. (Eng.) Popiela, T.; Szafran, Z.; Szafran, H.; Komorowska, M. (Nicholaus Copernicus Medical Acad., ul. Pradnicka, 37, 31-202 Krakow, Poland). *Gut* 18(3):208-213; 1977.

A study of gastric secretion was performed in nine male patients (mean age, 36 yr; age range, 27-52 yr) with duodenal ulcers before and 1-17 months after truncal vagotomy with pyloroplasty. Free and total hydrogen ion (H^+) concentrations and total protein and pepsin levels were measured in gastric secretion collected after the stomach was emptied and following stimulation by 0.008-8.192 μg/kg/hr pentagastrin, i.v. The graded doses were applied consecutively, each dose was infused for 30 min, and 18 10-min fractions of gastric juice were collected during the infusion. After vagotomy, the free and total H^+ concentrations were lower both in the basal state and in response to pentagastrin. Undissociated acidity, representing the difference between total and free H^+ concentrations was significantly ($p<0.05$) lower but did not demonstrate a dose-response relationship. The non-pepsin protein level increased significantly in 5th to 18th gastric juice samples and total protein in 9th to 18th samples in vagotomized patients. Only pepsin protein responded to pentagastrin stimulation. No correlation was observed between undissociated H^+ concentration and non-pepsin protein level either before or after vagotomy in contrast with previous studies in healthy patients that have demonstrated a correlation.

8181 ULTRASTRUCTURES OF G CELLS AND THE MECHANISM OF GASTRIN RELEASE BEFORE AND AFTER SELECTIVE VAGOTOMY WITH PYLOROPLASTY. (Eng.) Miyagami, H.; Watanabe, Y.; Sawada, Y.; Kato, K.; Shono, K.; Kondo, K.; Kidokoro, T. (Juntendo Univ. Sch. Medicine, 2-1-1 Hongo, Bunkyo-ku, Tokyo 113, Japan). *Arch. Histol. Jpn.* 40(1):51-62; 1977.

To assess the function of the retained antrum in patients with duodenal ulcer undergoing selective vagotomy (SV) plus pyloroplasty (P), plasma gastrin was measured and biopsied gastrin (G) cells were examined in eight patients who had SV + P surgery and eight patients who had SV plus antrectomy (A). The gastrin was measured by radioimmunoassay when patients were in the basal state (after overnight fast) and then 10, 20, 30, 40, 50, 60 min after infusion of 150 ml of beef broth or after i.v. injection of insulin, 0.2-0.3 U/kg. Levels of gastrin were measured in all patients before and 1, 3, 6, 12, and 24 months after surgery. G cells were examined ultrastructurally in biopsies obtained by fiberscope before and periodically after surgery of the eight SV + P patients. Basal gastrin levels were significantly ($p<0.01$) increased one month postoperatively in SV + P patients compared to SV + A patients. The SV + P patients also demonstrated elevated gastrin levels in response to meat extract or insulin hypoglycemia. The G cells after SV + P showed no degenerative or hypofunctional changes. Six months postoperatively G cell hyperplasia was apparent in the SV + P patients. It is concluded that the response of G cells to luminal stimuli is not essentially related to the presence of an intact vagus nerve.

SMALL INTESTINE

8190 DUODENAL ARTERIO-MESENTERIC OCCLUSION IN CHAGAS' DISEASE. (Spa.) Kunzle, J. E.; de Britto-Costa, R.; Ziliotto, A., Jr. (Servicio de Cirugia de Riberao Preto, Calle Garibaldi 1271, Riberao Preto, Sao Paulo, Brazil). *Bol. Chil. Parasitol.* 31(1/2):2-5; 1976.

All cases of arterio-mesenteric occlusion diagnosed from July 1960 to April 1975 and recorded in the Archives of the Riberao Preto Surgical Service were reviewed to verify the possibility that Chagas' disease may be a causative agent of such duodenal occlusions. Eight cases of arterio-mesenteric occlusion of the duodenum were discovered among 2,753 patients who underwent digestive tract surgery. In seven of these eight cases, the complement fixation test for Chagas' disease was positive, and signs of cardiopathy (4/7) and/or none or more of the enteropathies associated with the trypanosomiasis, namely dysphagia (2/7), esophagomegaly (3/7), intestinal constipation (2/7), and megacolon (1/7), were also observed. The only female patient demonstrated neither cardiopathy nor enteropathy. Comparing similar causal studies published in Brazil in the last 40 yr, it is suggested that Chagas' disease may be a contributing factor in the genesis of arterio-mesenteric duodenal ileus in Latin America.

8191 INFLAMMATORY CELL COUNT AND IDENTIFICATION IN CHRONIC NON SPECIFIC DUODENITIS. (Eng.) Cheli, R.; Giacosa, A. (Divisione di Gastroenterologia, Ospedali Civili di Genova, Genoa, Italy). *Endoscopy* 9(2):91-95; 1977.

Inflammatory cells were counted in duodenal biopsies from 5 patients with superficial duodenitis (SD), 4 with atrophic duodenitis (AD), and 3 with interstitial duodenitis (ID) and compared with counts in biopsies from 10 normal controls. Lymphocyte counts in the epithelium (cells/mm) were significantly ($p<0.01$) elevated in SD (91.0 ± 23.1), AD (119.0 ± 18.2), and ID (109.0 ± 14.3) with respect to controls (46.4 ± 12.7). Total cell counts in the lamina propria (cells/mm^2) were significantly ($p<0.01$) increased in SD (8,468 ± 568) and AD (13,950 ± 466) with respect to controls (5,213 ± 599), and these increases were due to significant ($p<0.01$) increases in plasma cells (5,448 ± 1,067 and 9,985 ± 1,024 for SD and AD, resp.) with respect to controls (1,823 ± 224). In the lamina propria of the ID biopsies, significant ($p<0.01$) increases in total cells were observed both in the peripheral (25,586 ± 1,216) and central (10,913 ± 896) inflammatory areas. These increases were due exclusively to increases in lymphocyte counts, which equaled the total counts in both inflammatory areas compared with a control value of 1,910 ± 279. Thus, significant increases in inflammatory cells were seen in all cases of chronic nonspecific duodenitis, with different patterns of increases being observed in the different histological conditions.

8192 ROLE OF INTESTINAL MICROFLORA IN COLONIC PSEUDO-OBSTRUCTION COMPLICATING JEJUNOILEA BYPASS. (Eng.) Barry, R. E.; Chow, A. W.; Billesdon, J. (Bristol Royal Infirmary, Bristol, England). *Gut* 18(5):356-359; 1977.

A double-blind crossover study using placebo and antibiotics effective against either aerobic or anaerobic organisms was carried out to elucidate the role of intestinal microflora in the pathogenesis of colonic pseudo-obstruction complicating jejunoileal bypass. Quantitative bacterial studies of the intestinal flora in the region of bypassed bowel were correlated with symptoms of abdominal pain and distension. Antibiotics effective against obligate anaerobes rapidly relieved the symptoms of pseudo-obstruction, and this coincided with the disappearance of these organisms from this region of bowel. Symptoms rapidly recurred when anaerobic organisms repopulated the bowel. It is concluded that obligate anaerobes may play a role in the pathogenesis of this complication.

8193 BYPASS ENTEROPATHY: AN INFLAMMATORY PROCESS IN THE EXCLUDED SEGMENT WITH SYSTEMIC COMPLICATIONS. (Eng.) Drenick, E. J.; Ament, M. E.; Finegold, S. M.; Passaro, E., Jr. (Veterans Admin. Wadsworth Hosp., Los Angeles, CA 90073). *Am. J. Clin. Nutr.* 30(1):76-89; 1977.

The natural course and treatment modalities of bypass enteropathy were assessed in 28 obese subjects. End-to-end anastomosis of 12 inches of proximal jejunum to 6 inches of distal ileum with drainage of the excluded small bowel into the sigmoid was carried out in 25 patients, and end-to-side jejunoileal anastomosis was carried out in 3. Invasion of the excluded segment by fecal flora was associated with a histologically demonstrable inflammatory response of the mucosa. The disorder was of variable severity and duration and occurred in the majority of the patients. Progression to a clinical syndrome resembling an acute abdomen occurred in about 15% of the patients. Small bowel ileus, and in some patients, obstruction of the colon were suggested by physical signs and x-ray findings. Surgical exploration in such instances demonstrated an inflammatory process of the excluded small bowel loops with severe distention of this segment and of the colon, but no organic obstruction. Pneumatosis cystoides intestinalis occurred in two patients. Exudative protein loss was documented in the severe cases. Most of the systemic sequelae are comparable to those seen with inflammatory bowel diseases. Fever, excessive weight and lean tissue loss, and the involvement of skin, blood vessels, joints, and possibly, the liver suggest an immune response as a common factor in the pathogenesis. The clinical improvement with antibiotics such as metronidazole or with restitution of normal bowel continuity indicates that the bacterial flora or their byproducts in the excluded small bowel segment are causally related to the systemic complications. Hyperoxaluria may be primarily the sequela of steatorrhea and not of the inflammatory process.

8194 MORPHOLOGICAL CHANGES OF THE ADAPTING SMALL INTESTINE UNDER VARIOUS CONDITIONS. AN EXPERIMENTAL AND CLINICAL STUDY. (Eng.) Fenyo, G. (Surgical Res. Lab., Karolinska sjukhuset, Stockholm, Sweden). *Acta. Chir. Scand.* 469(Suppl.):1-31; 1976.

Factors governing the mechanisms of intestinal adaptation and the reversibility of these changes were investigated in six experiments. Morphological changes were studied in 17 patients who underwent a jejunoileal bypass (JIB) because of severe obesity and then a second operation, mainly for cholelithiasis, persisting obesity, and cicatricial hernia. The other experiments were conducted in Sprague-Dawley rats. In the patients, the second JIB was followed by a significant elongation of the jejunal (43.69 ± 2.23 to 58.35 ± 4.27 cm, $p<0.05$) and ileal (14.13 ± 0.98 to 24.46 ± 2.23 cm, $p<0.001$) segments. Villous height also increased significantly ($p<0.001$) in the jejunum (682 ± 26 to 913 ± 62 μm) and ileum (582 ± 39 to 994 ± 85 μm), but it decreased at the top of the bypassed blind loop (682 ± 26 to 475 ± 36 μm, $p< 0.001$). These changes seem to form the basis of a concomitant functional adaptation that results in a deceleration of weight loss, leading to a period of stable weight or weight gain. A JIB in the rat resulted in significant hypertrophy of the functioning jejunal and ileal segments and the distal part of the blind loop. The top of this loop atrophied. These changes stopped 4 weeks after reestablishment of the normal intestinal anatomy, i.e., they were reversible. Continuous mechanical stimulation of isolated small intestinal segments (Thiry-Vella loops) diminished the atrophy that occurred in unstimulated segments. Shunt-operated rats fed a chemical diet (Vivasorb, lipid- and bulk-free) developed hypertrophic adaptive changes (HAC) similar to but more pronounced than those occurring in pellet-fed animals. Shunt-operated rats nourished only parenterally for 2 weeks developed HAC that were proportionally similar but more pronounced than those in pellet-fed rats. Shunt-operated rats with duodenopancreaticobiliary (DPB) diversion to the transverse colon developed HAC of the functioning jejunal and ileal segments. Thus, the presence of DPB secretions is not required for morphological adaptation.

SMALL INTESTINE

Malabsorption

8225 ACRODERMATITIS ENTEROPATHICA, ZINC, AND THE PANETH CELL: A CASE REPORT WITH FAMILY STUDIES. (Eng.) Bohane, T. D.; Cutz, E.; Hamilton, J. R.; Gall, D. G. (Hosp. Sick Children, 555 University Ave., Toronto, Ontario M5G 1X8, Canada). *Gastroenterology* 73(3):587-592; 1977.

The clinical, biochemical, and histological response to p.o. zinc therapy was studied in an infant with acrodermatitis enteropathica. The patient received zinc sulfate heptahydrate (150 mg/day), and clinical recovery was rapid; diarrhea ceased, dermatitis and irritability decreased, and appetite improved within 2 weeks. The plasma zinc and serum and mucosal alkaline phosphatase activities returned to normal. Light microscopy of small intestinal biopsies showed a normal mucosa. Electron microscopy of the Paneth cells initially revealed abnormal inclusion bodies that disappeared during therapy, suggesting that the abnormality is secondary to zinc deficiency, and not a primary defect. These abnormal inclusions may represent altered secretory granules and a proliferation of lysosomes.

8226 MALABSORPTION, VILLOUS ATROPHY, AND EXCESSIVE SERUM IgA IN A PATIENT WITH UNUSUAL INTESTINAL IMMUNOCYTE INFILTRATION. (Eng.) Baklien, K.; Fausa, O.; Brandtzaeg, P.; Froland, S. S.; Gjone, E. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(4):421-432; 1977.

The case of a patient with malabsorption, villous atrophy, and excessive serum immunoglobulin A is presented. The distribution of the cell population responsible for the overproduction of IgA was studied, and the transfer of IgA into various exocrine body fluids was examined. The patient presented at age 11 with gastrointestinal complaints of about 4 yr duration. The clinical symptoms disappeared in association with gluten withdrawal. During the subsequent 10 yr, however, the villous atrophy persisted, and malabsorption tests were unchanged. Moreover, his serum level of IgA remained extremely high (58-66 g/l), along with normal IgM and IgG. His IgA was mainly polymeric and showed polyclonal characteristics. Immunohistochemical investigations demonstrated that the gastrointestinal mucosa was its major production site. About 96% of the intestinal immunocytes were of the IgA class. An increased number of IgA-producing cells was also present in gastric mucosa, whereas nasal mucosa and bone marrow showed no abnormality, and peripheral blood contained a normal number of IgA-bearing lymphocytes. The polymeric IgA permeated dermal and mucosal connective tissue in high concentrations and appeared in the urine, but there was no marked elevation of secretory IgA levels in duodenal and salivary fluids. Nevertheless, staining of glandular epithelia indicated normal transport of IgA and the presence of secretory component (SC), and saliva contained IgA-associated as well as free SC. A defect in its external transport does not seem to be involved in the excessive contribution of dimeric IgA to serum. This case may bear some relation to α-chain disease or celiac disease.

8227 HYPEROXALURIA AND CALCIUM OXALATE NEPHROLITHIASIS AFTER JEJUNOILEAL BYPASS. (Eng.) Stauffer, J. Q. (Upstate Medical Center, Syracuse, NY). *Am. J. Clin. Nutr.* 30(1):64-71; 1977.

SMALL INTESTINE

Hyperoxaluria in patients with intestinal disease is discussed. Patients with ileal disease, ileal resection, and jejunoileal bypass are at increased risk of forming calcium oxalate renal calculi because of their enhanced absorption of dietary oxalate. Intraluminal solubility of oxalate is an important determinant for oxalate hyperabsorption, and it can be regulated by the intraluminal concentrations of calcium and fatty acids. Malabsorbed bile salts and fatty acids may alter intestinal permeability, leading to increased passive diffusion of oxalate. The management of hyperoxaluria includes a low-oxalate (<50 mg/day), low-saturated-fat, modest-calcium diet (750 mg/day); cholestyramine (CT) administration; the substitution of medium-chain triglycerides for saturated fats; and correction of the cause of steatorrhea. In patients with regional enteritis and bile salt diarrhea, CT not only controls the diarrhea but also reduces urinary oxalate excretion. CT has not been as effective in reducing oxalate excretion in patients who have undergone jejunoileal bypass, and it may lead to more-severe bile salt depletion in these subjects. However, selected patients with jejunoileal bypass who have recurrent calcium oxalate nephrolithiasis may obtain additional benefit from CT.

LARGE INTESTINE

8233 A PHASE II STUDY OF TRIAZINATE (NSC 139105) IN ADVANCED COLORECTAL CARCINOMA. (Eng.) McCreary, R. H.; Moertel, C. G.; Schutt, A. J.; O'Connell, M. J.; Hahn, R. G.; Reitemeier, R. J.; *et al.* (Dept. Oncology, Mayo Clinic, Rochester, MN 55901). *Cancer* 40(1):9-13; 1977.

The therapeutic activity of triazinate, a reversible inhibitor of dihydrofolate reductase, in advanced colorectal carcinoma and its effect on various immunologic determinants were studied. Triazinate was administered to 28 patients as a single agent in a 3-day course at a maximum clinically tolerable dosage (250 mg/m^2/day i.v.). Patients were evaluated at 3 and 6 weeks and then monthly until progression was evident. The principal side-effects were dermatitis (17), stomatitis (12), diarrhea (15), nausea (13), somnolence (6), and leukopenia (12). There were two drug-related deaths, both occurring in patients with slightly elevated serum creatinine values (1.3 mg/dl) and alkaline phosphatase values that were greater than two times normal (828 and 739 U/l, resp.). Triazinate appeared to have no discernible effect upon immunologic determinants, as demonstrated by recall skin tests, dinitrochlorobenzene sensitization, lymphocyte counts, and circulating T- and B-cell counts. An objective response occurred in 5/28 patients, 1 of whom is now without evidence of malignancy after 42 weeks. The overall response rate of 18% suggests that triazinate has a definite, although limited, effect upon advanced colorectal carcinoma. Further evaluation of triazinate in advanced phase II disease and studies of its role in combined drug regimens are suggested.

8234 DIETARY FIBRE, TRANSIT-TIME, FAECAL BACTERIA, STEROIDS, AND COLON CANCER IN TWO SCANDINAVIAN POPULATIONS. REPORT FROM THE INTERNATIONAL AGENCY FOR RESEARCH ON CANCER INTESTINAL MICROECOLOGY GROUP. (Eng.) MacLennan, R. (International Agency for Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France). *Lancet* 2(8031): 207-211; 1977.

Dietary intake and fecal characteristics, e.g., transit time, fecal bacteria, and fecal steroids, wer compared in population samples from Copenhagen, Denmark, and Kuopio, Finland. The two populations, which have similar Scandinavian cultures, have a fourfold difference in colon cancer incidence. The Copenhagen population (high-risk) consumed significantly ($p<0.05$) more white bread, meat, beer, wine, and spirits and less potatoes and milk. The Kuopio population had a higher intake of protein and energy ($p<0.001$) than the Copenhagen population. Dietary-fiber intake was also significantly higher ($p<0.001$) in Kuopio (30.9 g) than in Copenhagen (17.2 g). There was no difference in the frequency of defecation, although constipation was more frequent in the Copenhagen population (27% versus 12%). In spring and autumn, the mean stool weights in Copenhagen were 157 and 146 g, resp.; those in Kuopio were 175 and 211 g, resp. Bacteroids were more common and eubacteria and enterococci were less common in fecal specimens in Copenhagen. There was no difference in fecal steroid concentration between the two populations. It is suggested that the etiology of colon cancer is multifactorial and that it is not associated in a simple manner with dietary fat and neutral and acid steroids or their bacterial metabolites. Higher intakes of dietary fiber and milk in the low-incidence area suggest a possible protective effect, unrelated to mouth-anus transit time. Further studies are suggested to clarify the carcinogenic and protective effects of diet.

8235 BLUE RUBBER BLEB NEVUS SYNDROME: REPORT OF A CASE. (Eng.) Nakagawara, G.; Asano, E.; Kimura, S.; Akimoto, R.; Miyazaki, I. (Faculty Medicine, Kanazawa Univ., Kanazawa, Japan). *Dis. Colon Rectum* 20(5):421-427; 1977.

The surgical treatment of a 21-yr-old man with the blue rubber bleb nevus syndrome involving the digestive tract is reported. As a result of repeated losses of blood in the stool, the patient had severe anemia that could no longer be controlled by conservative therapy. On admission for surgery, there were 90 hemangiomas, ranging from 1-3 mm in diameter, all over the body. Five hemangiomas had been found within 75 cm of the anus by sigmoidoscopy 3 yr previously, when fluoroscopic examination of the large intestine showed no abnormality. However, the same examination at the present admission revealed a large filling defect in the central part of the transverse colon. At surgery, a giant mass of granular hemangiomas was resected from the center of the transverse colon. Hemangiomas protruding from the serous membranes of the stomach, small intestine, and colon were enucleated. Histologic examination revealed that the submucous tissue of the intestinal tract was almost entirely occupied by cavernous hemangiomas; in some areas the hemangiomas extended from the tunica muscularis to the serous membrane. The postoperative course was uneventful, and the patient is now under observation. A review of 26 reported cases of blue rubber bleb nevus syndrome reveals a correlation between the number of hemangiomas on the body surface and the number involving the digestive tract, or the severity of anemia.

8236 GANGRENE AND SPONTANEOUS PERFORATION OF THE CECUM AS A COMPLICATION OF PSEUDO-OBSTRUCTION OF THE COLON: REPORT OF THREE CASES AND SPECULATION AS TO ETIOLOGY. (Eng.) Spira, I. A.; Wolff, W. I. (Beth Israel Medical Center, 10 Nathan D. Perlman Place, New York, NY 10003). *Dis. Colon Rectum* 19(6):557-562; 1976.

Three cases of pseudo-obstruction of the colon in which the complications of cecal perforation and cecel gangrene supervened are presented, and the literature is reviewed. The first patient, a 71-yr-old woman, developed signs of colon obstruction while in the hospital recovering from a myocardial infarction. Gangrene of the cecum and colon and a hematoma near the celiac plexus were observed at laparotomy, but there was no evidence of mechanical obstruction or vascular occlusion. The patient died 7 days after a hemicolectomy was performed. The other two patients were men, age 52 and 62 yr, who entered the hospital because of abdominal pain and pneumonia, resp. Emergency surgery was required for these patients because of perforation of the cecum. Although signs of obstruction had preceded surgery, no evidence of mechanical obstruction was seen. The literature shows that pseudo-obstruction can complicate a variety of conditions, including normal or cesarian birth, cardiac failure, pneumonia, etc.; however, in many patients no etiological factor can be found. A discussion of possible etiological mechanisms implicates interference with the sympathetic-parasympathetic nervous system balance.

8237 IMMUNOHISTOCHEMICAL CHANGES IN MORPHOLOGICALLY INVOLVED AND UNINVOLVED COLONIC MUCOSA OF PATIENTS WITH IDIOPATHIC PROCTITIS. (Eng.) Das, K. M.; Erber, W. F.; Rubinstein, A. (Albert Einstein Coll. Medicine, Bronx, NY 10461). *J. Clin. Invest.* 59(3):379-385; 1977.

Alterations in secretory component, IgA, IgG, and IgM were studied by immunofluorescent techniques in mucosal biopsy specimens obtained at colonoscopy from inflamed and grossly uninvolved colonic mucosa from 12 patients with idiopathic proctitis. Extra-intestinal parotid salivary secretory component and IgA, as well as serum IgA, were also measured for the sake of comparison with colonic secretory component and IgA. Significant decreases in secretory IgA were observed in sections of colonic epithelium showing gross and histological proctitis in 8 of 12 patients. Significantly decreased secretory IgA levels were also observed in the proximal uninvolved colonic mucosa from five patients. Serum and salivary IgA levels, however, were not significantly diminished from control ranges of 77-257 mg/100 ml and 0.56-2.2 mg/100 ml, resp. The depletion of colonic secretory IgA in the face of normal salivary and serum IgA in these patients suggests that a local immune defect may be pathogenetically related to idiopathic proctitis.

8263 HISTOCOMPATIBILITY ANTIGENS IN INFLAMMATORY BOWEL DISEASE: THEIR CLINICAL SIGNIFICANCE AND THEIR ASSOCIATION WITH ARTHROPATHY WITH SPECIAL REFERENCE TO HLA-B27 (W27). (Eng.) Mallas, E. G.; Mackintosh, P.; Asquith, P.; Cooke, W. T. (Regional Transfusion Center, Birmingham, England). *Gut* 17(11):906-910; 1976.

The histocompatibility antigen (HLA) phenotypes were studied in 100 patients with ulcerative colitis (UC), 100 patients with Crohn's disease (CD), and 283 normal controls, with special reference to HLA-B27 and the phenotype of patients complicated with arthropathy. Of the 24 antigens tested, no significant difference at the 5% level was found for the HLA-A antigens in either disease group or for the HLA-B antigens in CD, compared with controls. There was, however, a significant ($p<0.05$) difference in locus HLA-B between UC and controls, even when cases of ankylosing spondylitis were excluded. Five UC patients also had ankylosing spondylitis, and four of these were HLA-B27 positive. Six UC patients had sacroileitis, three of whom were HLA-B-27 positive. Of CD patients, 2 also had ankylosing spondylitis, 1 of whom was HLA-B27 positive, and 11 had sacroileitis, 4 of whom were HLA-B27 positive. Twelve UC patients and 17 of those with CD had seronegative (enteropathic) peripheral arthropathy. Eleven CD patients with seronegative arthropathy had an HLA-A2, B12 phenotype combination, while only eight of the nonarthropathy patients had this combination ($p<0.01$). None of the UC patients had the HLA-A2, B12 combination; no patient with peripheral arthropathy had the HLA-B27 phenotype. The frequency of the HLA-B27 phenotype was 14% in UC, 6% in CD, and 6.7% in normal controls. Twelve of 14 UC patients with the HLA-B27 phenotype had total colonic involvement, while only 30 CD patients without this phenotype had total involvement ($p<0.024$). In CD, 5 of 6 B27-positive patients had total colonic involvement, while 17 B27-negative patients had it ($p<0.03$). It is concluded that the HLA-B27 phenotype may have prognostic and clinical significance in determining the extent and severity of inflammatory bowel disease, and it may play a role in differentiating the complications of this entity.

8264 HLA ANTIGENS AND ULCERATIVE COLITIS IN JAPAN. (Eng.) Tsuchiya, M.; Yoshida, T.; Asakura, H.; Hibi, T.; Ono, A.; Mizuno, Y.; Tsuji, K. (Sch. Medicine, Keio Univ., Tokyo, Japan). *Digestion* 15(4):286-294; 1977.

The relationship between the histocompatibility (HLA) antigen system and ulcerative colitis (UC) was studied in 44 Japanese patients with UC and 271 normal Japanese subjects. In the normal group, the most frequent HLA phenotypes were A-9 (60.9%), B-5 (40.6%), BW-40 (39.5%), A-2 (37.3%), A-10 (24.7%), AW-30/31 (20.7%), and BW-35 (19.2%). Compared to Caucasians, they showed significantly higher prevalences of A-9, A-10, B-5, and BW-40 and much lower prevalences of A-1, A-3, B-8, B-14, and B-18. The UC patients differed significantly from the Japanese controls in having a much higher percentage of B-5 (72.7%, $p<0.001$) and lower percentages of A-2 (27.3%), BW-35 (4.5%), BW-40 (27.3%), and AW-30/31 (0%). In the UC patients, the B-5 phenotype was significantly elevated in women (81%) and patients with colonic involvement (81%); lower prevalences were seen in men (61%) and patients with proctitis only (37.5%). The most frequent HLA haplotypes in the controls were A9-B5, AW30/31-B12, and A9-B7. The A9-B5 haplotype was not found in the UC patients. A small number of family studies yielded no significant information on the HLA haplotype in UC or on the relationship between the mixed leukocyte culture locus (which is distinct from the HLA A or B locus) and UC.

PANCREAS

8267 THE CYTODIAGNOSTIC ASPECTS OF PURE PANCREATIC JUICE OBTAINED AT THE TIME OF ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (E.R.C.P.). (Eng.) Smithies, A.; Hatfield, A. R. W.; Brown, B. E. (Clinical Res. Center, Harrow, Middlesex, England). *Acta Cytol. (Baltimore)* 21(2):191-195; 1977.

Cytologic studies were made of the pure pancreatic juice collected at the time of endoscopic retrograde cholangiopancreatography (ERCP) from 61 patients undergoing investigation for pancreatic or biliary disease. A large number of degenerate cells were observed in the pure pancreatic juice from all 26 patients with pancreatic cancer and all 9 patients with pancreatitis. Degenerate cells were found in only 4/26 remaining patients finally judged to have no pancreatic disease, and in these 4 the number of cells was scanty. When the degenerate cells reached a final stage of what appeared to be a degenerative process, the nuclei were karyorrhectic, and dense chromatin fragments were distributed peripherally in the cell. The cytoplasm was eosinophilic, and it had a rather solid appearance. Malignant cells were found in the pure pancreatic juice of 14/26 patients who were finally diagnosed at laparotomy or autopsy to have pancreatic carcinoma. In 18 of these patients, ERCP was diagnostic for carcinoma. With the combination of ERCP plus pure pancreatic juice cytology, a diagnosis was reached in 24/26 patients with pancreatic carcinoma.

8268 BIOAVAILABILITY OF FOOD IRON-(^{59}Fe), VITAMIN B_{12}-(^{60}Co) AND PROTEIN BOUND SELENOMETHIONINE-(^{75}Se) IN PANCREATIC EXOCRINE INSUFFICIENCY DUE TO CYSTIC FIBROSIS. (Eng.) Heinrich, H. C.; Gabbe, E. E.; Bartels, H.; Oppitz, K. H.; Bender-Gotze, Ch.; Pfau, A. A. (Univ. Hosp. Eppendorf, Univ. Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Klin. Wochenschr.* 55(12): 595-601; 1977.

The absorption of heme Fe [^{59}Fe-labeled hemoglobin (Hb) and pork Fe], nonheme Fe (ferritin in hog liver), ^{60}Co-labeled vitamin B_{12}, and ^{75}Se-selenomethionine-labeled pork was measured in children with pancreatic exocrine insufficiency due to cystic fibrosis. Children with normal or mildly reduced Fe stores absorbed 5.9-13% of a 5-mg Hb-Fe dose give p.o., 6.9-14% of a 5-mg dose of p.o. administered liver-Fe, and 17-34% of a 0.7- to 2.0-mg dose of p.o. administered pork-Fe. Two children with depleted Fe stores absorbed 19% of the Hb-Fe dose in each case, 12% and 28% of the liver-Fe dose, and 23% and 30% of the pork-Fe dose. These absorption values are within the ranges of Hb-, liver-, and pork-^{59}Fe absorption described for healthy adults with normal and depleted Fe stores, resp. Three children with cystic fibrosis absorbed only 0.5-2% of a 0.50-nmol dose of p.o. administered ^{60}Co-labeled vitamin B_{12}; this malabsorption was not influenced by the simultaneous administration of a potent purified hog intrinsic factor concentrate. Adults with normal intrinsic factor secretion absorb 40-95% of a 0.50 nmol dose of ^{60}Co-labeled vitamin B_{12}. Two children with cystic fibrosis absorbed 60-71% of the ^{75}Se from a p.o. dose of 200 g ^{75}Se-selenomethionine-labeled pork, whereas normal adults absorb 76-100% of the ^{75}Se. Pancreatin did not improve the bioavailability of ^{75}Se-selenomethionine from labeled pork in cystic fibrosis patients. These preliminary results indicate that the intraluminal peptic digestion of dietary protein is adequate in pancreatic insufficiency and that pancreatin treatment will not improve protein utilization in cystic fibrosis.

8269 ECHOGRAPHY FOR THE DIAGNOSIS OF PANCREATIC PSEUDOCYSTS. (Fre.) Arnaud, J. P.; Aprahamian, M.; Macler, J.; Renaud, R.; Adloff, M. (Centre Medico-Chirurgical, 19, rue L. Pasteur, 67300 Schiltigheim, France). *Ann. Chir.* 31(6):463-470; 1977.

PANCREAS

Pancreatitis

8271 FUNCTIONAL EXPLORATION OF CHRONIC PANCREATITIS BY DUODENAL INTUBATION. COMPARATIVE STUDY OF THE LUNDH MEAL AND DUODENAL HORMONES BASED ON A SURVEY OF LITERATURE. SECRETIN-CAERULEIN TEST CARRIED OUT BY THE AUTHORS. (Eng.) van der Hoeden, R.; Mesa, A. V.; Delcourt, A. (Institut medicochirurgical d'Ixelles, Rue J. Paquot 63, B-1050 Brussels, Belgium). *Acta Gastroenterol. Belg.* 39(11/12):509-521; 1976.

The Lundh and duodenal hormone tests for the diagnosis of chronic pancreatitis (CP) are described briefly and compared. In the Lundh test, pancreatic secretion is stimulated with a meal composed of 6% fat, 5% protein, and 15% carbohydrates. It is easy, inexpensive, and well-tolerated. In the hormone test, which is more sensitive, the pancreas is stimulated directly with secretin and pancreozymin. The use of a third, simplified test of submaximal stimulation of the pancreas with a secretin-cerulein perfusion is proposed based on experience with 34 CP patients, 17 liver disease patients, and 30 healthy controls. A duodenal intubation was performed, and secretin (1 U/kg/hr) was infused over 80 min accompanied, after 40 min, by cerulein (75 ng/kg/hr). The duodenal juice was aspirated manually every 10 min, and the volume and the concentrations and outputs of bicarbonate and amylase were measured. The differences between CP patients and controls with respect to bicarbonate and amylase output were significant ($p<0.001$). For example, the respective mean values at 70-80 min of perfusion were 1.25 and 5.40 mEq% for bicarbonate output and 2.5 and 4.3 U for amylase output. Differences in volume were less marked. Amylase and bicarbonate outputs were abnormal in 34 and 29 CP patients, resp. Use of the latter for liver disease should be restricted. Because of an increased choleretic response after secretin stimulation, the volume was higher than normal in these patients, and, as a result of low bicarbonate concentration in the bile, the net results were normal or higher output levels. This may mask a pancreatic insufficiency. To detect all stages of CP, the Lundh test should be used as a screen, followed, when indicated, by hormone stimulation with submaximal doses of secretin and cerulein.

8272 ON THE QUANTITATION OF ISO-AMYLASES IN SERUM AND THE DIAGNOSTIC VALUE OF SERUM PANCREATIC TYPE AMYLASE IN CHRONIC PANCREATITIS. (Eng.) Magid, E.; Horsing, M.; Rune, S. J. (Bispebjerg Hosp., Denmark). *Scand. J. Gastroenterol.* 12(5):621-627; 1977.

Studies were carried out in 142 normal subjects and in 95 patients with symptoms of chronic pancreatitis to assess whether the quantitative determination of serum pancreatic-type isoamylase can be used as a diagnostic test for exocrine pancreatic insufficiency. The normal appearance of serum amylase zymograms produced with an agarose electrophoresis technique is described, and the reference values from studies of the normal subjects for salivary and pancreatic type amylases are presented. In the 95 patients, exocrine pancreatic function was assessed by means of the Lundh meal test. A low serum pancreatic-type amylase value was found to indicate the presence of a reduced exocrine pancreatic function ($p=0.96$), and a normal or elevated serum pancreatic-type amylase value excluded the presence of a severe exocrine pancreatic insufficiency ($p=0.91$). An abnormal amylase fraction that may be of diagnostic significance in pancreatic disease was observed. Future studies of the occurrence of abnormal amylase isoenzymes may improve the diagnostic yield of serum isoamylase determinations.

8273 HAEMATOLOGICAL ABNORMALITIES IN ACUTE PANCREATITIS. A PROSPECTIVE STUDY. (Eng.) Murphy, D.; Imrie, C. W.; Davidson, J. F. (Radcliffe

Infirmary, Oxford, England). *Postgrad. Med. J.* 53(620):310-314; 1977.

Hematological and coagulation indices were studied in 25 patients with acute pancreatitis in the first week of their admission. Platelet counts initially fell and later returned to admission levels. Rising levels of plasma fibrinogen were recorded. The kaolin cephalin clotting time was shorter than its control in 21 patients. Eighteen patients had elevated fibrinogen degradation products, and 14 had a positive ethanol gelation test. It is suggested that, by taking into account the results in series of individual patients, a degree of intravascular coagulation may be a common feature of acute pancreatitis. In one patient (presented in detail) strong evidence for disseminated intravascular coagulation was found.

8274 CHRONIC PANCREATITIS: A CAUSE OF BILIARY STRICTURE. (Eng.) Schulte, W. J.; LaPorta, A. J.; Condon, R. E.; Unger, G. F.; Geenen, J. W.; DeCosse, J. J. (Wood Veterans Admin. Center, Wood, WI 53193). *Surgery* 82(3):303-309; 1977.

Experience with 13 patients who had a distal common duct stricture associated with chronic relapsing pancreatitis is presented. All patients, when first seen, had an elevated alkaline phosphatase level; 8 of 13 patients also had an elevated serum bilirubin level. Five of the jaundiced patients had a febrile course; a preoperative diagnosis of acute cholangitis was made in four of these. Eight of the 13 patients underwent a choledochoduodenostomy for relief of biliary obstruction; 7 of these patients are living and well, and 1 died of continued alcoholism and pancreatitis. One patient had a loop cholecystojejunostomy; decompression was inadequate, and death due to septicemia secondary to ascending cholangitis ensued. The biliary tract should be investigated in patients known to have chronic relapsing pancreatitis who also have persisting abdominal symptoms and an elevated alkaline phosphatase. If a stricture of the distal common bile duct is identified in the absence of acute pancreatitis, choledochoduodenostomy should be performed.

LIVER AND BILIARY TRACT

8281 LIVER HISTOLOGY IN A 'NORMAL' POPULATION: EXAMINATIONS OF 503 CONSECUTIVE FATAL TRAFFIC CASUALTIES. (Eng.) Hilden, M.; Christoffersen, P.; Juhl, E.; Dalgaard, J. B. (Inst Forensic Medicine, Univ. Aarhus, Aarhus, Denmark). *Scand. J. Gastroenterol.* 12(5):593-597; 1977.

The liver histology of 503 consecutive victims of fatal (within 24 hr) traffic accidents submitted to medico-legal autopsy were used to determine liver histology in a "normal" population. In 370 persons no pathological changes in the liver biopsies were observed. Fatty liver was found in 120 persons, nonspecific portal inflammation in 7, alcoholic hepatitis in 6, portal fibrosis in 5, and hemopoiesis was observed in 1 person. No cases of cirrhosis, chronic aggressive hepatitis, changes compatible with chronic persistent hepatitis or viral hepatitis, or other internationally accepted morphological diagnoses were found. A few focal necroses, distributed diffusely throughout the parenchyma, were found in 15 cases, and 8 cases showed slight variation in size of nuclei and/or cells. Six livers contained Mallory bodies. Alcoholic hepatitis was shown in all livers containing Mallory bodies. A slight degree of Kupffer cell proliferation was noted in 15 cases. A significant positive correlation ($p<0.01$) between the frequency of steatosis and age groups was demonstrable. Fatty liver was found in 1% of persons below 20 yr, in 18% of those 20-40 yr, and in 39% of those >60 yr. The persons with fatty liver had a higher body weight, but obesity was not correlated to age. It is concluded that fatty infiltration in the liver is a normal observation in aged persons. The results show that morphological liver diagnosis, except fatty liver, is very seldom found in this type of material.

8282 THE PRESENCE OF HEPATIC INTRAMITOCHONDRIAL CRYSTALLINE INCLUSIONS IN ROUTINE LIVER BIOPSIES. (Eng.) Mandel, E. M.; Lewinski, U.; Gafter, U.; Weiss, S.; Freidin, N.; Djaldetti, M. (Hasharon Hosp., Petah-Tiqva, Israel). *Am. J. Med. Sci.* 274(1):61-67; 1977.

Electron microscopic examination of the liver biopsies of 33 patients with liver disease revealed the presence of intramitochondrial crystalline inclusions (IMCI) in 10. The diagnosis of the patients with IMCI included one case each of alcoholism, cirrhosis, hyperlipidemia, hyperthyroidism, iron deficiency anemia, leptospirosis, malignant melanoma, and porphyria as well as two cases of metastatic hypernephroma. A comparison of patients with and without liver IMCI revealed no significant difference in age, hepatomegaly, elevated alkaline phosphatase levels, SGOT, SGPT, and BSP retention. The nature of the IMCI is unclear, and no common feature in patients with liver IMCI could be found to explain the existence of these inclusions.

8283 PROTEIN BINDING AND KINETICS OF DRUGS IN LIVER DISEASES. (Eng.) Blaschke, T. F. (Room S-155, Stanford Univ. Medical Center, Stanford, CA 94305). *Clin. Pharmacokinet.* 2(1):32-44; 1977.

Interrelationships between liver disorders and protein binding as they affect the disposition of drugs eliminated metabolically in man are discussed. Both the type or stage of liver disease and the pharmacokinetic characteristics of the drug influence the nature and magnitude of changes in drug disposition. At least two general mechanisms may be responsible for changes in the binding of drugs in liver disease patients. The concentration of albumin, the most important plasma protein responsible for drug binding, and therefore the total number of albumin binding sites are frequently reduced in these patients, and the globulin fractions may be increased. Changes in the fraction of bound drug produced by alterations in albumin or globulin will depend on the total drug concentration, number of binding sites, and the drug dissociation constants. Even in the absence of measurable changes in albumin concentration, the binding of drugs to plasma proteins may be decreased in liver disease patients, and mechanisms similar to those causing decreased drug binding in renal insufficiency may also be operative in these patients. Drugs for which changes in plasma protein binding in liver disease have been demonstrated include propranolol, morphine, diazepam, tolbutamide, phenylbutazone, phenytoin, thiopentone, quinidine, and amylobarbitone. Changes in hepatic clearance and/or volume of distribution in various liver diseases have been observed for such drugs as pethidine, lignocaine, propranolol, tolbutamide, diazepam, clindamycin, chlorpromazine, antipyrine, amobarbitone, hexobarbitone, and chloramphenicol. At present, there is no method for predicting the drug dose requirement for a patient at a particular stage of a liver disease.

8284 GUIDELINES TO CLEARING PATIENTS WITH LIVER DISEASE FOR SURGERY. (Eng.) Leibowitz, S. (325 East 16th St., New York, NY 10003). *Mt. Sinai J. Med. N.Y.* 44(4):539-543; 1977.

Guidelines for clearing liver disease patients for surgery are presented. If clinical, historical, and laboratory findings indicate recent acute liver disease, the patient should not be cleared for surgery unless the patient's life is threatened more by a postponement of surgery than by immediate intervention. A history of past liver disease (hepatitis, cirrhosis, toxic hepatitis) per se is not a bar to proceeding with necessary surgery, but, if time allows, a thorough workup should be performed before surgery to assess any current disease activity. If the screening of a patient with a history of prior liver disease reveals no evidence of significant disease, the patient may be cleared for emergency surgery. In these cases, elective surgery should be preceded by necessary baseline studies to determine the current disease activity. When there is evidence of current liver disease, the specific diagnosis should be made before surgery. Elective surgery is not recommended for acute viral hepatitis; when there is a need for major surgery (e.g., carcinoma of the gut), surgery should be postponed as long as possible until the condition subsides. Surgery is recommended as the lesser of two evils for life-threatening conditions (ruptured viscus or uncontrollable bleeding of a duodenal ulcer) in patients with acute viral hepatitis and acute toxic hepatitis. In cases of compensated cirrhosis of the liver, the degree of surgical need determines clearance. Surgery in cases of uncompensated liver cirrhosis should be aimed at correcting accompanying disorders of the liver disease such as portal hypertension (e.g., shunt surgery; surgery is always performed as an elective procedure when the patient has been maximally prepared. Immediate surgery is only performed to stop variceal hemorrhage. When the hepatic disease is secondary to the basic illness that surgery is intended to correct, carefully considered elective surgery is recommended.

8285 THE SPECTRUM AND CAUSES OF LIVER DISEASE IN NARCOTIC ADDICTS. (Eng.) Gelb, A. M.; Mildvan, D.; Stenger, R. J. (Beth Israel Medical Center, 10 Nathan D. Perlman Place, New York, NY 10003). *Am. J. Gastroenterol.* 67(4):314-318; 1977.

Factors involved in the development of liver disease among 50 narcotic addicts were analyzed. Two cases were unsuitable for analysis. Among 12 active heroin users or 30 former heroin addicts maintained on methadone, 32 were heavy alcohol abusers. Six patients were on alcohol alone. Of these 38 alcohol abusers, 17 had cirrhosis, which was confirmed by biopsy in 8 patients. Two patients died of liver failure. Among all 48 patients, 9 had clinical evidence of alcoholic hepatitis, while 10 had acute viral hepatitis and 2 showed biopsy evidence of chronic viral hepatitis. Reversible liver disease was seen in both alcohol abusers and nonalcoholics. This study suggests that alcohol is a major factor in the development of irreversible liver disease in active heroin addicts and ex-addicts on methadone maintenance. It is suggested that special strategies be devised for the management of alcoholism in addicts and ex-addicts on methadone.

8286 RECENT ADVANCES IN PEDIATRIC HEPATOLOGY. (Eng.) Alagille, D. (Hopital d'Enfants, 78 rue du General-Leclerc, 94270 Bicetre, France). *Pediatr. Res.* 11(9, Part 2):994-996; 1977.

The basic knowledge acquired concerning the physiology of neonatal hyperbilirubinemia, the transmission of hepatitis B virus to fetuses and infants, the relationship between alpha-l-antitrypsin deficiency and liver disease, the enzymatic disturbances in Reye's syndrome, and the surgical progress in extrahepatic biliary atresia and in early portal hypertension is summarized. Neonatal hyperbilirubinemia is attributed to a temporary imbalance between bilirubin production and clearance, created at birth by the abrupt deprivation of the placental transfer and clearance functions. The transmission of hepatitis B to fetuses and infants and the role of alpha-l-antitrypsin deficiency in biliary and liver disease in children remains unclear. Exchange transfusion, peritoneal dialysis, hemodialysis, and procedures aimed at cerebral decompression are only used with success when initiated at the early stage of the Reye's syndrome disease. The cure of extrahepatic biliary atresia by grafting remains doubtful. Three types of surgical procedures are described: 53 infants underwent hepatic porto-enterostomy (group 1); 20 infants underwent classical porto-enterostomy and jejunostomy (group 2); and 18 infants were treated by hepatic porto-cholecystostomy (group 3). Twenty patients in group 1, six patients in group 2, and seven patients in group 3 survived. Splenorenal anastomoses in children who had bleeding due to early portal hypertension is suggested. The choice of the proper surgical treatment must take into account the efficacy and operative risks of each procedure.

8287 α_1-ANTITRYPSIN DEFICIENCY AND INFANTILE LIVER DISEASE. (Eng.) McPhie, J. L.; Binnie, S.; Brunt, P. W. (Dept. Pathology, Univ. Medical Buildings, Foresterhill, Aberdeen AB9 2ZD, Scotland). *Arch. Dis. Child* 51(8):584-588; 1976.

The genetic nature of infantile liver disease caused by α_1-antitrypsin (AA) deficiency is illustrated by case histories from two families. The disease is inherited by a simple autosomal recessive pattern; PiM is the designation of the normal α_1-antitrypsin gene, and severe deficiency with levels of AA below 50 mg/100 ml are associated with the phenotype PiZZ. The characteristic evolution of the disease, observed in the two children in one family and three children in the other, commences with mild or severe neonatal hepatitis at age 3-4 weeks. The jaundice subsides in most infants in 3 weeks to several months, but cirrhosis develops. At about age of 3-4 yr the child has symptoms of ascites or hematemesis from esophageal varices. The patients usually die of hemorrhage or hepatic coma. Diagnosis can be readily made on basis of low AA serum levels and PAS-positive globular intracytoplasmic inclusion bodies, positive for AA, within the hepatocytes. Retrospective histological analysis of 61 liver biopsies of children and adolescents performed in a 13-yr period revealed that three children (5%) had evidence of AA deficiency liver disease.

8288 HEPATOCELLULAR CARCINOMA AND CHRONIC PERSISTENT HEPATITIS. (Eng.) Shikata, T.; Yamazaki, S.; Uzawa, T. (Nihon Univ. Sch. Medicine, Ohyaguchi-Kamimachi, Itabashiku, Tokyo 173, Japan). *Acta Pathol. Jpn.* 27(3):297-304; 1977.

The pathology files of 9,000 autopsy cases were surveyed to determine the association between hepatocellular carcinoma (HC) and liver cirrhosis or liver fibrosis. There were 603 cases of liver cirrhosis an 220 cases of HC. Of the latter, 85.8% were combined with liver cirrhosis, 8.0% with liver fibrosis; the remaining 6.2% were not associated with any other liver pathology. A study was also made of the presence of hepatitis B surface antigen (HBsAg) in the 19 HC cases for which paraffin sections were available. HBsAg was detected by orcein and aldehyde-fuchsin stain on 4/10 tissue specimens of HC associated with fibrosis, on 4/6 specimens of HC plus early cirrhosis, and 0/3 specimens of HC without other liver pathology. HBsAg was only observed on the noncancerous hepatocytes. It is concluded that liver fibrosis may be caused by chronic viral hepatitis. Liver fibrosis as well as cirrhosis may be considered precancerous pathology.

8289 SEQUENTIAL LOCOREGIONAL CHEMOTHERAPY OF LIVER CANCER IN ADULTS. (Fre.) Bessot, M.; Lorenzini, Cl.; Mauuary, G.; Fays, J.; Duprez,

A. (No affiliation given). *Ann. Chir. Infant.* 17(5/6):461-470; 1976.

The results of sequential locoregional chemotherapy in 110/140 adult patients with primary (37) and secondary (103) liver tumors are presented. Chemotherapy consisted of intra-arterial perfusions of 5-fluorouracil (250 mg) or methotrexate (10 mg) on days 1-4, followed by endoxan (100 mg) and vinblastine (1 mg) between days 4 and 5, and mitomycin (125 μg) or actinomycin D (100 μg) between days 5 and 6. This course was continued for 4-8 weeks at 15- to 30-day intervals until remission. Of the 110 patients given sequential chemotherapy, 60 responded to the treatment. The results were a decrease in hepatomegaly (23 patients), amelioration on scintigraphy (16), and regression of tumor mass or of hypervascularization (21). Of these 60 patients, 12 survived 1 yr. After chemotherapy, many patients could not withstand subsequent surgery for hepatic metastases or recurrence. Two types of complications developed during treatment--chemotherapy-induced hepatic coma and accidents due to long-term catheterization. Other complications included septicemia (6), acute ulcerations caused by displacement of the catheter (3), and atheromatous projection (3).

8290 THE RADIOLOGIC INVESTIGATION OF HEPATIC TUMORS IN CHILDHOOD.

(Eng.) Miller, J. H.; Gates, G. F.; Stanley, P. (Children's Hosp. Los Angeles, 4560 Sunset Blvd., Los Angeles, CA 90027). *Radiology* 124(2):451-458; 1977.

A scheme for the evaluation of abdominal masses in children using diagnostic modalities developed since 1970 is presented. Diagnosis should begin with a conventional x-ray of the abdomen, followed by inferior vena cavagraphy and excretory urography, then gray scale ultrasonography and radionuclide scintigraphy with ^{99m}Tc, and ending with angiography. This approach was used to examine 65 children, newborn to 17 yr (not every technique was needed in each case). Examination revealed 18 benign neoplasms, 20 malignant tumors, 8 nonneoplastic hepatic masses, and 12 glycogen storage disease cases. The radiographic analyses of the most common hepatic masses of children, hepatoblastomas, hepatic cell carcinomas, small cell sarcomas, hepatic adenoma, angiomatous tumor, hepatic abscess, neonatal hematoma, congenital neuroblastoma, and involuting tumor, are tabulated. The newer techniques permit differentiation between benign and malignant lesions and demonstrate the extent and exact location of the lesion. Chemotherapy of malignant tumors can be evaluated by nuclear imaging, ultrasound, and angiography.

8291 'BIG ACTH' AND CALCITONIN IN AN ECTOPIC HORMONE SECRETING TUMOUR OF THE LIVER.

(Eng.) Himsworth, R. L.; Bloomfield, G. A.; Coombes, R. C.; Ellison, M.; Gilkes, J. J. H.; Lowry, P. J.; *et al.* (Northwick Park Hosp., Harrow, Middlesex HA1 3UJ, England). *Clin. Endocrinol.* 7(1):45-62; 1977.

Plasma and tumor tissue hormones were studied in a 16-yr-old boy with rapidly developing Cushing's syndrome that was due to the ectopic secretion of ACTH and immunoreactive β-melanocyte stimulating hormone (β-MSH)-like material from hepatic tumor deposits, possibly originating from biliary radicals. Cushing's syndrome has not previously been described in association with a primary hepatic tumor. During the 22-month course of the illness, the plasma immunoreactive ACTH and β-MSH concentrations rose logarithmically. The plasma calcitonin concentration was also elevated, but it did not change during the final 12 months. The plasma concentration of the ecotopically produced hormones underwent acute variations: after hydrocortisone treatment, the variations were inconstant. During the course of the illness, the ectopic ACTH became biologically less potent. This ineffectual ACTH was present in a large molecular weight form in the plasma, in the tumor, and in the medium in which the tumor was cultured. This "big ACTH" differed from the normal ACTH in the patient's pituitary and from authentic ACTH in its immunochemical character; the C-terminal antigenic determinant (33-39 region of ACTH) was masked in the large molecular weight form but was uncovered after extraction in neutral buffer, and this "big ACTH" was more readily extracted from the tumor at pH 7.0. The tumor tissue also contained immunoreactive β-MSH and immunoreactive calcitonin that resembled calcitonin M chromatographically.

8292 STUDIES ON ISOENZYMES IN RELATION TO CANCER. II. SERUM ALDOLASE ISOENZYME PATTERNS IN THE DIAGNOSIS OF PRIMARY HEPATOCELLULAR CARCINOMA.

(Eng.) Damle, S. R.; Talavdekar, R. V. (Tata Memorial Hosp., Parel, Bombay-400 012, India). *Indian J. Cancer* 14(2):145-150; 1977.

Aldolase isoenzyme patterns were studied by agarose gel electrophoresis in the sera of 58 patients with primary hepatoma and compared with those in sera of 192 patients with different malignant conditions and 46 patients with different liver diseases. The characteristic pattern found in the hepatoma patients consisted of a predominant muscle-type aldolase band accompanied by a band hybridized with brain-type aldolase. This pattern was not observed in the controls with other malignant diseases or in those with benign liver diseases. The presence of this atypical pattern occurred in 80% of the hepatoma patients. It is concluded that the study of aldolase isoenzyme patterns may prove to be a useful adjunct to other biochemical profiles in the diagnosis of primary hepatoma.

8293 HEPATIC TUMORS: POSSIBLE RELATIONSHIP TO USE OF ORAL CONTRACEPTIVES.

(Eng.) Klatskin, G. (Dept. Medicine, Yale Univ., 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 73(2):386-394; 1977.

A review of the literature up to September 1976 reveals 117 cases of hepatic tumors in women using oral contraceptives (O.C.) and an additional 120 cases possibly associated with O.C. use. The data on these cases are tabulated on the basis of tumor histology; type of O.C. and duration of use; presenting symptoms; hepatic function, scintiscan, and arteriographic abnormalities; and clinical course. The O.C. included almost all combinations of synthetic estrogens and progestogens in common use; however, those containing mestranol as the estrogenic component outnumbered those containing ethinyl estradiol. In patients with hepatic cell adenoma (120), the presenting complaint was usually acute abdominal pain accompanied by shock due to tumor rupture. About half of the patients with focal nodular hyperplasia (96) had asymptomatic tumors; acute pain was the most common symptom in the other half. Scintiscans and arteriography detected hepatic abnormalities in almost all reported cases; however, hepatic function was not usually altered, and tests were usually negative. Only 8/107 patients with a benign hepatic pathology died, and all deaths were attributed to rupture with hemoperitoneum (4 occurred after surgery, 3 prior to surgery, 1 after hepatic artery ligation). Five of the eight patients with malignant hepatic tumors died (1 during surgery, 1 a year after lobectomy).

8294 CURRENT CONCEPTS IN INTRAHEPATIC CHOLESTASIS. (Eng.) Schwarz, L. R.; Schwenk, M.; Greim, H. (Dept. Toxicology, Gesellschaft fur Strahlen- und Umweltforschung, Ingolstadter Landstrasse 1, D-8042 Neuherberg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 24(3):210-215; 1977.

The pathogenesis of intrahepatic cholestasis is discussed. Drug-induced intrahepatic cholestasis appears to be primarily due to a biochemical interference with cellular functions at the molecular level. The most common drugs used to induce cholestasis experimentally are steroid hormones and lithocholate. One target of these compounds may be the lipid phase of several cell structures, such as the sinusoidal and canalicular membranes, the endoplasmic reticulum, and the mitochondria. By their capacity to interact with the lipid layer and membrane proteins, cholestatic compounds impair specific cellular functions such as carrier protein activity, hydroxylation, and mitochondrial ATP synthesis. Other targets of cholestatic compounds may be the binding proteins in the cytoplasm and, possibly, the microfilaments. The initiating event of drug-induced intrahepatic cholestasis is unknown, and it is not clear whether the increased bile acid levels in the blood are the cause or consequence of intrahepatic cholestasis.

8295 THIAMINE DEFICIENCY IN FULMINANT HEPATIC FAILURE AND EFFECTS OF SUPPLEMENTATION. (Eng.) Labadarios, D.; Rossouw, J. E.; McConnell, J. B.; Davis, M.; Williams, R. (King's Coll. Hosp. and Medical Sch., London SE5 8RX, England). *J. Vitam. Nutr. Res.* 47(1):17-22; 1977.

The response to i.v. supplementation with thiamine (thiamine hydrochloride, 100 mg b.i.d.) plus vitamins was investigated in 8/24 patients with acute hepatocellular damage leading to fulminating hepatic failure. Mean erythrocyte transketolase activity (ETA) was significantly lower in these patients than in controls (33.8 ± 2.6 and 41.8 ± 1.7 U/l, resp., $p<0.025$). In six of eight patients the *in vitro* stimulation of ETA by the added thiamine, which is converted into thiamine pyrophosphate (TPP effect), was >25%, providing evidence of TPP deficiency. The TPP effect was significantly higher ($p<0.05$) in these patients (18 ± 2.8%) than in controls (10.6 ± 2.2%). There was no correlation between urinary thiamine excretion and ETA. ETA was increased significantly ($p<0.025$) from 38.3 ± 4.1 U/l on admission to 53.7 ± 6.9 U/l on day 3 in the eight patients receiving vitamin supplements. Concomitantly, there was a progressive and significant decrease to normal TPP effect values on the third (7.0 ± 2.0%, $p<0.05$) and seventh (4.2 ± 2.0%, $p<0.025$) days of supplementation. In the 16 patients who did not receive vitamin supplements, there was an increase in the TPP effect, evidence of increasing thiamine deficiency. These studies indicate that conversion of thiamine hydrochloride to its biologically active coenzyme form, thiamine pyrophosphate, is possible even in the presence of severe acute hepatocellular necrosis. Vitamin supplements should be included in the routine management of patients with acute hepatic failure.

8296 LIVER PROTOCOLLAGEN PROLINE HYDROXYLASE IN HUMAN LIVER DISEASES AND EXPERIMENTAL LIVER FIBROSIS. (Eng.) Tsujii, T.; Kimura, K.; Fukuhara, M.; Morita, T.; Matsui, T.; Tamura, M.; Matsuoka, Y. (Nara Medical Univ., 840 Shijocho, Kashiwara City, Nara 634, Japan). *Gastroenterol. Jpn.* 12(1):21-27; 1977.

Hepatic procollagen proline hydroxylase (PPH) activity was determined in 33 patients with various liver diseases, in rats with CCl_4-induced liver fibrosis, and in rats with choline deficiency (CD) fatty liver. PPH activity (disintegrations/min ^{3}H-hydroxyproline/mg protein) was highest (4-9 times that of controls) in persistent hepatitis patients, followed by patients with liver cirrhosis (2-8 times higher), chronic active hepatitis (x3), chronic inactive hepatitis (x2), and acute hepatitis (x2). PPH activity in the one patient with a fatty liver was lower than that in controls. Even though the persistent hepatitis patients had only a negligible or slight amount of fibrosis, their activity was similar to that of the liver cirrhosis patients. PPH activity correlated with the serum monoamine oxidase ($r=0.461$, $p<0.05$), serum alkaline phosphatase ($r=0.445$, $p<0.05$), and indocyanine green retention tests ($r=0.530$, $p<0.05$). Hepatic PPH activities in both groups of rats rose with time. Between 23 and 31 weeks after the start of the experiment, the activity was slightly lower in CD fatty liver rats without fibrosis than in those with fibrosis. However, the activity of the former was still considerably higher than that of control rats. It is concluded that there is a relation between PPH activity and liver pathology.

8297 FOCAL NODULAR HYPERPLASIA OF THE LIVER: POSSIBLE INFLUENCE OF FEMALE REPRODUCTIVE STEROIDS ON THE HISTOLOGICAL PICTURE. (Eng.) Moesner, J.; Baunsgaard, P.; Starklint, H.; Thommesen, N. (Patologisk Institut, Amtssygehuset, DK-8000 Aarhus, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(2):113-121; 1977.

Eighteen patients with focal nodular hyperplasia (FNH) of the liver were studied to evaluate possible histological differences between FNH patients who had taken female sex hormones and those who had no history of hormone treatment. Characteristic histological changes were found in the lesions of four women who had taken oral contraceptives for 4-7 yr (lesion 4.0-10.5 cm maximum diameter) and one man who had taken diethylstilbestrol (30 mg/day) for prostatic carcinoma for 2 yr until death. These lesions consisted of young connective tissue septa with a pronounced bile duct proliferation, piecemeal necrosis, and lymphocytic infiltration. Smaller nodes (0.3 to 2.2 cm maximum diameter) containing much less or no activity were found in the remaining 13 patients who had not been treated with hormones. Possible mechanisms for the effect of the female reproductive steroids are discussed. It is proposed that FNH represents a congenital malformation, possibly a hamartoma. The liver cells of this hamartoma may suffer from enzymatic defects, which may render them especially vulnerable to female sex hormones, resulting in secondary changes of the liver parenchyma, blood vessels, and bile ducts of the lesion.

8298 HEPATIC METABOLIC CHANGES FOLLOWING ENERGY DEPRIVATION BY AMMONIA IN PATIENTS AND RABBITS WITH JAUNDICE. (Eng.) Kamiyama, Y.; Takeda, H.; Ohshita, M.; Nambu, H.; Yamaoka, Y.; Yamamoto, M.; Kimura, K.; Ozawa, K.; Honjo, I. (Kyoto Univ. Faculty Medicine, Kyoto, Japan). *Surg. Gynecol. Obstet.* 145(1):33-40; 1977.

The effect of ammonia on the energy metabolism of the severely damaged human and rabbit liver was investigated. The ammonia concentrations in portal and venous blood and peripheral arterial blood remained unchanged during the study period, although the concentration in portal blood was about four times that in peripheral blood. Hepatic carbamoyl phosphate synthetase I and ornithine carbamoyl transferase activities did not decrease in patients with obstructive jaundice and in rabbits subjected to ligation of the common bile duct. In these rabbits, the adenylate energy charge level fell rapidly to a mean of 0.780 ± 0.024, compared with 0.866 ± 0.003 for rabbits that were fed normally ($p<0.05$). Their mortality rate increased with decrease of the hepatic energy charge, which was accompanied by a decrease in ATP content (to 1.712 ± 0.034 μmol/g liver, from a control value of 2.743 ± 0.046; $p<0.05$) and an increase in ADP content (to 0.774 ± 0.018 μmol/g liver, from a control value of 0.643 ± 0.024; $p<0.05$). Mitochondrial phosphorylative activity and citrulline synthesizing ability decreased significantly ($p<0.05$). The latter was restored by the addition of exogenous ATP to the medium. I.p. loading of ammonium chloride in experimental rabbits caused hyperammonemia and an additional decrease in the energy charge and ATP content in the liver. The energy charge and ATP content were negatively correlated with arterial blood ammonia ($p<0.001$). The results suggest that ammonia from the intestinal tract is fixed preferentially in the severely damaged liver, in which energy metabolism is impaired to a level at which the tissue can no longer function adequately, and that it leads to the depletion of large amounts of hepatic energy.

8299 PELIOSIS HEPATIS: TWELVE CASES ASSOCIATED WITH ORAL ANDROGEN THERAPY. (Eng.) Nadell, J.; Kosek, J. (Stanford Univ. Sch. Medicine, Palo Alto, CA 94304). *Arch. Pathol. Lab. Med.* 101 (8):405-410; 1977.

Twelve cases of peliosis hepatis associated with high-dose androgen therapy are reviewed. Eleven patients had received up to 200 mg/day of p.o. oxymetholone for 1.5-19 months. Three of the 11 also had received a second agent; 1 had received 30 mg/day of p.o. methyl testosterone for 3 months and 2 had received 200 or 400 mg/week of i.m. testosterone for 10 and 14 months, resp. The twelfth patient had received an unknown amount of fluoxymesterone. In three patients, liver failure was the primary cause of death. In one patient, the diagnosis was established by biopsy, the androgen therapy was discontinued, and the lesion was absent at autopsy 2 yr later. In eight patients, peliosis hepatis was an incidental finding at postmortem examination. The liver was about twice the normal weight in nine patients, normal in two, and smaller than normal in one. Previously reported cases of peliosis are reviewed briefly.

8300 TREATMENT OF PORPHYRIA CUTANEA TARDA WITH CHLOROQUINE AND PHLEBOTOMY. (Eng.) Swanbeck, G.; Wennersten, G. (Sahlgren's Hosp., S-413 45, Goteborg, Sweden). *Br. J. Dermatol.* 97(1):77-81; 1977.

Chloroquine (CQ) therapy alone or in combination with phlebotomy was used to treat 11 patients with porphyria cutanea tarda (PCT). In nine patients, one to four venesections were performed (at 3-to-7-day intervals, 300 ml blood being removed each time) prior to the p.o. administration of CQ phosphate (250 mg/day) for 7 days. The two patients who were treated with CQ only developed fever (39.6 and 38.6 C), nausea, vomiting, and myalgia. One of these patients, when treated 2 yr later with two venesections before CQ administration, still reacted with fever (39.0 C), slight nausea, and headache. The other nine patients experienced no troublesome clinical reactions, although five noticed slight nausea. In all patients, urinary porphyrin excretion rose rapidly, and hepatic enzyme levels were at their highest near the end of CQ therapy. Porphyrin excretion and serum hepatic levels diminished rapidly during the first month after treatment and then fell progressively over the next several months, mostly to levels well below the pretreatment level. There seemed to be no correlation between the number of venesections performed before treatment and the porphyrin excretion or hepatic enzyme levels. When three apparently normal siblings in a family in which the mother and one of the children had PCT were treated with CQ in an attempt to uncover a postulated latent PCT, no clinical reactions or biochemical manifestations resulted.

8301 ULTRASTRUCTURAL ABNORMALITIES OF LIVER CELLS IN REYE'S SYNDROME. (Eng.) Iancu, T. C.; Mason, W. H.; Neustein, H. B. (Childrens Hosp. Los Angeles, 4650 Sunset Blvd., Los Angeles, CA 90027). *Hum. Pathol.* 8(4):421-431; 1977.

The ultrastructure of liver biopsy specimens from nine infants and children with Reye's syndrome was studied. Excessive fat content was the most striking abnormality, and it occurred in all specimens. Mitochondrial abnormalities were also frequent. However, no correlation could be established between the severity of the mitochondrial changes and clinical or biochemical data, and two patients with low levels of the first two urea cycle enzymes showed only mild mitochondrial abnormalities. Nonspecific or artifactual factors have been suggested to explain the mitochondrial changes; however, the data suggest that most of the reported mitochondrial abnormalities are not artifacts and that they can be helpful in the ultrastructural diagnosis of Reye's syndrome.

8302 SICKLE CELL HEPATOPATHY. (Eng.) Sheehy, T. W. (Veterans Admin. Hosp., 700 S. 19th St., Birmingham, AL 35233). *South. Med. J.* 70(5): 533-538; 1977.

The incidence and course of hepatobiliary complications of sickle cell anemia (SSA, 88 patients) and viral hepatitis (67 patients) in black patients are reviewed. Only 5/88 SSA patients had viral hepatitis; none of the 67 viral hepatitis patients had SSA, but 4 had the sickle cell trait. Twenty-eight hepatic crises occurred in 8/88 SSA patients, during which their SGOT levels ranged from 48 to 179 IU, serum alkaline phosphatase levels from 100 to 290 IU, and serum bilirubin levels from 2.1 to 12.9 mg%. Liver function tests were transiently abnormal in 26/42 SSA patients with extrahepatic crises. Hepatic crisis should be differentiated from acute cholecystitis or viral hepatitis. Cirrhosis is relatively common and is often the terminal event in SSA; 3/6 patients who died had cirrhosis. Choledocholithiasis (1 patient) and cholecystitis (7 patients) are infrequent complications, despite the prevalence of cholelithiasis (11 patients).

8303 HEPATIC LIPID METABOLISM IN SEVERE HUMAN OBESITY. (Eng.) Kral, J. G.; Lundholm, K.; Bjorntorp, P.; Sjostrom, L.; Schersten, T. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Metab. Clin. Exp.* 26(9):1025-1031; 1977.

To elucidate mechanisms underlying steatosis, lipid and protein syntheses were studied in 17 morbidly obese patients and 17 normal controls. The rate of incorporation of glycerol-carbon into triglyceride (TG) in liver slices from the normolipoproteinemic patients during jejunoileal bypass was significantly elevated compared with the controls (280 ± 16 μmol/hr/kg versus 209 ± 15 μmol/hr/kg, $p<0.01$). The obese patients had an almost sevenfold increase in hepatic TG content as well. None of the patients had manifest diabetes, though increased basal levels of insulin and impaired glucose tolerance during p.o. glucose tolerance tests (OGTT) were common. There were statistically significant positive Spearman rank correlations between plasma insulin levels and TG synthesis ($r=0.57$, $p<0.01$), TG content ($r=0.54$, $p<0.01$), and serum fatty acids ($r=0.52$, $p<0.05$). The basal insulin levels were also positively correlated to the incorporation rate of fructose-carbon into fatty acids ($r=0.47$, $p<0.05$). The sum of insulin values during OGTT showed a trend toward positive correlation with the hepatic cholesterol content ($r=0.34$, $p<0.10$). The hepatic protein content as well as the rate of leucine-carbon incorporation into proteins did not differ from controls. However, there was a trend toward a negative correlation between protein synthesis and basal plasma insulin levels ($r=-0.33$, $p<0.10$). Liver steatosis in severely obese patients may be due to significantly increased hepatic lipid synthesis in the face of elevated levels of serum fatty acids.

8304 THE MECHANISMS OF HEMOLYSIS IN WILSON'S DISEASE: STUDY OF A CASE AND REVIEW OF THE LITERATURE. (Eng.) Meyer, R. J.; Zalusky, R. (Mount Sinai Sch. Medicine, Fifth Ave. and 100 St., New York, NY 10029). *Mt. Sinai J. Med.* 44(4):530-538; 1977.

The mechanisms of hemolysis were studied in a 17-yr-old girl with Wilson's disease during a phase of active hemolysis. Her RBC reduced glutathione content was low and had abnormal stability. RBC enzyme activities were normal or increased, and hemoglobin stability, hemoglobin oxygen affinity, and RBC deformability were all normal. Copper-induced oxidative stress has been incriminated as the cause of hemolysis in Wilson's disease, although supporting data is equivocal. In previous studies, supraphysiological copper concentrations added *in vitro* have been shown to affect glucose-6-phosphate dehydrogenase, GSH, and GSH stability with increased formation of Heinz bodies. These findings do not appear to adequately explain the degree of hemolysis observed, either in this patient or in others described in the literature. Copper-induced damage or alteration of the RBC membrane requires futher study.

8305 HEPATOLENTICULAR DEGENERATION (WILSON'S DISEASE) AND PREGNANCY. A REVIEW AND REPORT OF A CASE. (Eng.) Toaff, R.; Toaff, M. E.; Peyser, M. R.; Streifler, M. (Hakiryah Maternity Hosp., Tel-Aviv, Israel). *Obstet. Gynecol. Surv.* 32(8):497-507; 1977.

Wilson's disease (WD), or hepatocellular degeneration, is an inherited metabolic dysfunction of Cu metabolism. Its manifestations, which are variable and may develop gradually or suddenly, include extrapyramidal disturbances, mental and emotional disturbances, postnecrotic cirrhosis of the liver (leading to splenomegaly, ascites, jaundice, hepatomegaly, hematemesis, and spider angiomas), acute hemolytic anemia, Kayser-Fleischer rings, and renal tubular dysfunction. The nature of the metabolic error in WD remains obscure. The fertility of women affected by WD is impaired markedly. However, because of the current efficacy of penicillamine (PA) treatment, pregnancies in these patients will be more common in the future. In this review, the relation of WD to many areas of obstetric physiology are evaluated: effect of Cu and WD on fertility and on a normal pregnancy, effect of pregnancy on the natural history of WD, effect of WD on the newborn, potential dangers and actual effect of PA treatment during pregnancy, and association between WD and hypertensive disorders of pregnancy. A table summarizes the available clinical data on nine successful pregnancies in WD reported in the literature. Six occurred in PA-treated patients, one in a Versanate/2,3-dimercaptopropanol-treated patient. In four of these patients, pregnancy was associated with a remission of symptoms that lasted a few weeks to 6 months after delivery. Also included is the detailed case report of a young woman with WD who had two successful pregnancies. Upon diagnosis of the disease at age 13, she was treated with 750 mg/day PA until her first pregnancy at age 21, when the dose was reduced to 150 mg x 3. Her second pregnancy began 6 months after the first delivery. Percutaneous renal and liver biopsies performed immediately after each delivery were normal.

8306 ORTHOTOPIC LIVER TRANSPLANTATION: THE FIRST 60 PATIENTS. (Eng.) Calne, R. Y.; Williams, R. (Addenbrooke's Hosp., Cambridge CB2 2QQ, England). *Br. Med. J.* 1(6059):471-476; 1977.

Experience gained from 60 orthoptic liver transplants carried out between May 1968 and 31 December 1976 is presented. Of the 35 patients operated on before 1973, 12 died within the first postoperative week, but there were no deaths within this period in patients operated on in 1975 and 1976. During this period there were changes in the selection of patients and their management. Initially, some patients were operated on when they were too ill, often because of a prolonged wait for a donor. There was a high incidence of fatal complications of biliary drainage in patients who survived longer than the first week after operation. An analysis of the first 33 patients showed that 14 of the 22 who survived the immediate operation developed biliary fistulae. Improved results have been due to the development of a simple method of preserving the liver, thereby increasing the pool of potential donors, and by a new technique of biliary drainage, which allows well vascularized anastomoses without tension, retains the sphincter of Oddi, and leaves access for radiological examination of the biliary tree. Uncontrollable rejection of the liver occurred in less than 10% of cases. This contrasts strongly with the incidence of rejection among kidney transplants. Fourteen of the 60 patients lived for over 6 months, and 6 patients lived for over 1 yr, the longest surviving for more than 5 yr, and 13 patients were still alive at the beginning of 1977.

8307 OBSERVATIONS ON PRESERVATION, BILE DRAINAGE AND REJECTION IN 64 HUMAN ORTHOTOPIC LIVER ALLOGRAFTS. (Eng.) Calne, R. Y.; McMaster, P.; Portmann, B.; Wall, W. J.; Williams, R. (Dept. Surgery, Univ. Cambridge, Cambridge, England). *Ann. Surg.* 186(3):282-290; 1977.

Current changes in the management of patients undergoing orthotopic liver allografts in one hospital are presented, on the basis of experience with 64 patients operated on between 1968 and 1977. Many patients were referred for liver grafting late in the course of their diseases and were operated on when they were extremely ill, or they died before suitable livers could be found. Complications of biliary drainage were the most frequent causes of death. In the past 2 yr, a method of liver preservation that permits up to 8 hr of safe storage, without any complicated machines, has been used, and 22 livers have been transported by air and road from other institutions. This has enlarged the pool of potential donors and therefore reduced the average waiting time for a liver transplant. A new method of biliary drainage has been employed in 24 patients using the vascularized gallbladder as a conduit between the donor and recipient common ducts. This procedure has resulted in a marked reduction in early postoperative complications of biliary fistula and obstructed bile drainage. Following 35 allografts carried out between 1968 and 1974, 11 recipients died during the first postoperative week, 19 died between the 1st week and the 6th month, 2 died between the 6th month and the 1st year, and only 1 patient was still alive in 1977. None of the 29 patients who underwent surgery between 1975 and 1977 died during the 1st week; 10 died between the 1st week and the 6th month, 4 died between the 6th month and 1st yr, and 14 were still alive in 1977. Now that survival has been improved, it has become clear that uncontrollable rejection of the allografted liver in man is much less severe than that experienced with kidney transplants. The results of liver grafting in this unit during the past year are better than those obtained with kidneys from cadaver donors.

8308 USE OF HIGH DOSE ALPHA-MERCAPTOPROPIONILGLYCINE IN CHRONIC LIVER DISEASES. (Ita.) Cafiero, M.; Buono, G.; Ussano, L.; Sensale, P. (Ente Ospedaliero Generale S. Camillo, Napoli, Italy). *Rass. Int. Clin. Ter.* 56(18):1108-1111; 1976.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

8336 SYNERGISM BETWEEN OXYTOCIN ADMINISTRATION IN THE MOTHER AND HYPERBILIRUBINEMIA IN THE NEONATE. (Ita.) Patriarca, P. L.; Zorzi, L.; Petrelli, G. P.; Zecca, G.; Terenzi, P. (Ospedale Generale di Zona, Morbegno, Italy). *Minerva Med.* 29(21):1335-1339; 1977.

A retrospective study was made of 1,020 normal births that occurred over a 2-yr period in Morbegno Hospital. The 1,020 births were subdivided into three groups: group A consisted of 376 neonates whose mothers did not receive oxytocin to induce or stimulate labor; group B consisted of 334 neonates whose mothers received ≤3 IU of oxytocin; group C consisted of 310 neonates whose mothers received >3 IU of oxytocin either to induce or to stimulate labor. The number of cases of neonatal icterus with bilirubinemia of ≥12 mg% was calculated for each group. In group A, there were 27 such cases of icterus, in group B, 20 cases (not statistically different from the incidence rate for group A), and in group C, 41 cases, a significantly higher incidence than in either groups A or B. The hyperbilirubinemic effect of oxytocin appears to be dose-dependent. It is suggested that the protocols for induction and stimulation of labor with oxytocin be reviewed.

8337 IMMUNE COMPETENCE ASSESSMENT IN HYPERBILIRUBINEMIC NEWBORNS BEFORE AND AFTER PHOTOTHERAPY. (Eng.) Rubaltelli, F. F.; Piovesan, A. L.; Semenzato, G.; Barbato, A.; Ongaro, G. (Clinica Pediatrica dell'Universita di Padova, 35100 Padova, Italy). *Helv. Paediatr. Acta* 32(2):129-133; 1977.

Tests for immune competence in six normal and six hyperbilirubinemic newborns were assessed before and after phototherapy. The lymphoproliferative response to phytohemagglutinin in the hyperbilirubinemic infants was inhibited in the presence of autologous plasma in comparison with normal infants and normal adults. The phototherapy thus does not seem to inhibit the lymphoproliferative response. After phototherapy, an increased level of IgM and a slight decrease in IgG concentration were found. These data support the possibility that phototherapy is not contraindicated during septic hyperbilirubinemia.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

8339 LIVER FUNCTION AND STRUCTURE IN SURVIVORS OF ACETAMINOPHEN POISONING: A FOLLOW-UP STUDY OF SERUM BILE ACIDS AND LIVER HISTOLOGY. (Eng.) Hamlyn, A. N.; Douglas, A. P.; James, O. F. W.; Lesna, M.; Watson, A. J. (Univ. Newcastle upon Tyne Medical Sch., Newcastle upon Tyne, NE1 4LP, England). *Am. J. Dig. Dis.* 22(7):605-610; 1977.

Liver function and structure in 30 patients, hospitalized with acetaminophen overdose, were studied during initial admission and again 3 months later. The quantity of acetaminophen ingested varied from 5-50 g, and 19 patients developed raised serum transaminase levels during the initial period. Liver damage, on the basis of needle biopsy findings, was categorized as severe in 5, moderate in 7, and mild or minimal in 18 patients. At 3 months follow-up all but one of the biochemical indicants of liver damage had reverted to normal in all patients. The exception was the serum total bile acids. Residual changes found on liver biopsy at 3 months were minimal and nonspecific, apart from one previously severely affected patient in whom there was evidence of scarring. It is concluded that in the usual spectrum of acetaminophen poisoning requiring hospitalization, there is no evidence of lasting liver damage.

8340 HEPATITIS DUE TO ERYTHROMYCIN PROPIONATE. (Fre.) Pessayre, D.; Marie, C.; Benhamou, J. P. (Unite de Recherches de Physiopathologie Hepatique, Hopital Beaujon, F 92110 Clichy, France). *Arch. Fr. Mal. App. Dig.* 65(5):405-408; 1976.

Erythromycin propionate (EP) was implicated in inducing hepatitis in a 58-yr-old man treated for furunculosis. Following daily treatment with 2 g EP for 9 days, he complained of abdominal pain, asthenia, and a feeling of dizziness. The drug was discontinued, but 2 days later icterus appeared and the feces and urine were discolored. The serum bilirubin level was 40 mg/l, and the SGPT and alkaline phosphatase levels rose to five and two times their normal values, resp.; eosinophilia was also present. Icterus persisted for 8 days. The biochemical values returned to normal 2 weeks later. Challenge with 500 mg EP resulted in the reappearance of the original complaints, which lasted for 3 days. They were accompanied by vomiting, a rise in SGPT and serum bilirubin values, and eosinophilia. These reactions disappeared after 10 days. Subsequent oral cholecystography revealed normal bile ducts.

8341 EFFECT OF URIDINE AND UDPG ON GALACTOSAMINE INDUCED HEPATITIS IN THE RAT. (Ita.) Zonta, N.; Mantovani, E.; Bescape, F. (IV Cattedra di Farmacologia dell'Universita di Milano, Milan, Italy). *Atti Accad. Med. Lomb.* 31(2):133-135; 1976.

The effect of uridine and uridine diphosphoglucose (UDPG) on galactosamine-induced hepatitis was studied in adult female rats. Groups of 12 rats received 2 mM/kg galactosamine i.p. followed at 3, 5, and 8 hr by either 2 mM/kg uridine i.p. or 2 mM/kg UDPG i.p. Control animals received physiological saline only. Animals were sacrificed 24 hr after treatment and SGOT, SGPT, lactic dehydrogenase, bilirubin, and total lipid levels in the liver were determined. Both UDPG and uridine were effective in reducing enzyme and bilirubin levels to near normal, although UDPG was slightly more effective in all instances. UDPG was more effective than uridine in reducing total lipids. The reason for the superiority of UDPG over uridine in these studies was not determined.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

8348 HEPATITIS AND OPERATING-ROOM PERSONNEL: AN APPROACH TO DIAGNOSIS AND MANAGEMENT. (Eng.) Naulty, J. S.; Reves, J. G.; Tobey, R. E.; Schultz, W. W. (George Washington Univ. Sch. Medicine, Washington, DC). *Anesth. Analg. (Cleve.)* 56(3):366-372; 1977.

Hepatitis is twice as frequent in health care workers as in the general population, and the incidence in operating room (OR) personnel is even higher. Although the cause of the higher incidence has not been established definitely, possible explanations included frequent handling of blood products, contact with the oral secretions and serum of viral hepatitis patients, and exposure to hepatotoxic chemicals such as halothane and chloroform. Viral hepatitis can be diagnosed readily by radioimmunoassay techniques. At present, halothane-induced hepatitis can be deduced only by ruling out viral infection.

8349 STUDIES OF AN OUTBREAK OF ACUTE HEPATITIS A: II. ANTIBODY CHANGES TO CYTOMEGALOVIRUS AND HERPESVIRUS. (Eng.) Baer, G. M.; Yager, P. A.; Hierholzer, J. C.; Walker, J. A.; Almeida, J. D. (Bureau of Epidemiology, Center for Disease Control, CDC Lawrenceville Facility, Lawrenceville, GA). *J. Med. Virol.* 1(1):9-14; 1977.

The presence of antibody changes to 70 viral antigens was investigated in the acute and convalescent sera from 14 school children with acute hepatitis A and in sera from 9 sex- and age-matched healthy classmates. The children were 6-12 yr, and the outbreak of hepatitis was from a contaminated water source. In a few children with hepatitis, low but stable complement-fixing antibody titers were observed for parainfluenza, adenoviruses, mumps, rubella, and Coxsackie viruses, but the rise or fall was not more than twofold. Marked decreases, reaching levels fourfold or greater, in antibody to cytomegalovirus were noted in sera of 5/14 children with hepatitis and in antibody to herpesvirus 1 in sera of 3 of the sick children. No such changes in antibody levels against viral antigens were observed in sera of the matched healthy controls. Antibody changes appeared to be related to the degree of illness, since they were noted in four of six children with icterus.

8350 INTERFERON PRODUCTION AND ROLE OF α_2-MACROGLOBULIN IN THE IMMUNE RESPONSE DURING HUMAN VIRAL HEPATITIS A. (Fre.) Bador, H.; Colobert, L.; Giroud, M.; Lesbre, F. (Faculte de Medecine Alexis-Carrel, rue Guillaume Paradin, 69008 Lyon, France). *Clin. Chim. Acta* 78(2):217-226; 1977.

The immunological characteristics of 31 patients with the monophasic and polyphasic forms of viral hepatitis A are described. The hepatitis was diagnosed as A rather than B on the basis of the absence of the Australia antigen, sudden onset with high fever, absence of arthritic signs or urticaria, and the epidemic origin. Interferon levels followed a biphasic pattern in both monophasic and polyphasic hepatitis A. Study of the immunoglobulins revealed a different pattern between the two forms only for IgG. In monophasic hepatitis, IgG levels were only slightly elevated (to 1,500 mg/100 ml from a normal value of 1,130 mg/100 ml) during the first month, after which they slowly returned to normal values. In polyphasic hepatitis A, however, the IgG levels rose to >1,600 mg/100 ml during the first month, after which they continued to rise to >1,900 mg/100 ml. In both forms of hepatitis A, IgM was increased markedly during the first month (to nearly 400 mg/100 ml from a normal value of 145 mg/100 ml), followed by a return to normal levels, but the IgA level remained unchanged. α_2-Macroglobulin rose to above-normal levels (>230 mg/100 ml) only during convalescence of the monophasic patients, but they rose as early as the first 30 days of illness in the polyphasic patients. The macroglobulin levels remained elevated for several months in the latter, which may account for the immunological injury to the virus-infected hepatocytes and for the prolongation of infection in polyphasic patients.

8351 THE ANTIBODY RESPONSE FOLLOWING HEPATITIS A INFECTION. (Eng.) Locarnini, S. A.; Ferris, A. A.; Lehmann, N. I.; Gust, I. E. (Monash Medical Sch., Alfred Hosp., Commercial Rd., Prahran, Victoria 3181, Australia). *Intervirology* 8(5):309-318; 1977.

The development of antibody to hepatitis A virus of the IgM class (anti-HAV IgM) was studied in serial serum specimens from 10 patients with confirmed hepatitis A infection. A specific IgM response to hepatitis A virus was detected in sera from all patients, using immune electron microscopy and solid-phase radioimmunoassay. The presence of virus-specific IgM in 19S components of acute and early convalescent phase sera was detected. Virus-specific IgM was demonstrated in whole serum specimens by indirect immunoferritin labeling. Following acute infection, however, the major immunoglobulin response appears to be IgG, since titers of specific 7S and whole serum antibody were very similar.

8352 ACUTE INFECTIOUS HEPATITIS. CLINICAL AND EPIDEMIOLOGICAL STUDY. (Eng.) Canosa, C. A.; Gosalvez, J. A.; Abeledo, G.; Dalmau, J. (Children's Hospital, Social Security "La Fe," Alferez Provisional 21, Valencia, Spain). *Helv. Paediatr. Acta* 32(1):21-28; 1977.

Data on 120 children, age 0-7 yr, hospitalized in the period 1971-1974 for acute infectious hepatitis are presented. Only the most serious cases were admitted to this regional children's hospital. The disease was diagnosed in 5% of all hospital admissions, and its seasonal distribution did not follow the expected epidemiological pattern. The presence or absence of the Australian hepatitis antigen (HbAg) was correlated with the nutritional status, blood groups, clinical signs and symptoms (hepatomegaly, jaundice, choluria, etc.), blood and other biochemical findings, morbidity, and mortality. Children with blood group A$^+$ were four times as likely to be HbAg negative as those with other blood groups; O$^+$ children were more than twice as likely to be HbAg positive. Nutritional status played an important role in the incidence and seriousness of the disease, since a high percentage of the children were malnourished or small for their age. Bilirubin, SGOT, SGPT, and LDH were the most sensitive indicators of disease evolution. Complete clinical and biochemical recovery usually occurred within 30 days of admission, but there was a mortality rate of 2.5%.

8353 SEX DIFFERENCES IN RESPONSE TO HEPATITIS B INFECTION AMONG PATIENTS RECEIVING CHRONIC DIALYSIS TREATMENT. (Eng.) London, W. T.; Drew, J. S. (Fox Chase Cancer Center, Philadelphia, PA 19111). *Proc. Natl. Acad. Sci. U.S.A.* 74(6):2561-2563; 1977.

The hypothesis that with equal exposure there is no sex difference in response to hepatitis B virus (HBV) was tested. Patients undergoing treatment at a community-based renal dialysis clinic were monitored monthly for hepatitis B surface antigen (HBsAg) and antibody to HBsAg (anti-HBs). Of 160 patients who began treatment HBsAg-negative/anti-HBs-negative, 77 subsequently became HBsAg-positive. Once HBsAg-positive, males were more likely to remain HBsAg-positive indefinitely, whereas females were more likely to convert to HBsAg-negative and develop anti-HBs. This was not due to a sex difference in exposure to hepatitis B virus because only patients who became infected while undergoing treatment were included in the analysis. These data are clear evidence of a sex difference in response to hepatitis B virus, which may partially explain the greater incidence of several chronic liver diseases, including primary hepatocellular carcinoma, in males.

8354 IMMUNE RESPONSES TO THE HEPATITIS B SURFACE ANTIGEN AND LIVER-SPECIFIC LIPOPROTEIN IN ACUTE TYPE B HEPATITIS. (Eng.) Lee, W. M.; Reed, W. D.; Osman, C. G.; Vahrman, J.; Zuckerman, A. J.; Eddleston, A. L. W. F.; Williams, R. (Columbia Univ. Coll. Physicians and Surgeons, 630 W. 168th St., New York, NY 10032). *Gut* 18(3):250-257; 1977.

A serial prospective study of cellular immunity to hepatitis B surface antigen (HBsAg) and liver-specific membrane lipoprotein was carried out in 21 adults with acute hepatitis type B. Thymus-derived (T) lymphocytes reacting with HBsAg on the surface of infected hepatocytes may destroy these cells and also initiate an anutoimmune reaction responsible for continued liver damage in chronic active hepatitis. Cellular immunity to HBsAg, as determined by leukocyte migration inhibition with partially purified HBsAg as antigen, was detected in all the patients during the recovery phase of the illness and was already detectable at the time of admission in 13 (62%) patients. In five of the remaining eight, the titer of HBsAg in the serum at admission was high, and in the whole series, there was an inverse correlation between the degree of migration inhibition on admission and the peak HBsAg titer, suggesting that antigen or antigen/antibody complexes might be interfering with the demonstration of cellular immunity *in vitro*. Using a combination of minimum migration index recorded during the recovery period and peak HBsAg titer, the peak aspartate aminotransferase level was computed with reasonable accuracy, a finding consistent with the hypothesis that the severity of the illness is related to both the number of infected hepatocytes and the vigor of the immune response to HBsAg. Evidence of an immune response to the liver-specific hepatocyte membrane lipoprotein was present in 50% of the patients tested at the time of admission, but was transient, having disappeared in every case by 4 weeks. The minimum migration index recorded with HBsAg as antigen was significantly lower in patients with detectable sensitization to the lipoprotein, and it is possible that this autoimmune reaction is also generated by the interaction of T cells with viral antigenic determinants on the liver cell surface.

8355 NUCLEAR FLUORESCENCE OF LIVER CELLS FOR IgG IN VIRAL HEPATITIS B: SIGNIFICANCE AND RELATION TO HEPATITIS B-CORE AND ANTI-HEPATITIS B-CORE FORMATION. (Eng.) Gudat, F.; Bianchi, L.; Finch, M.; Krey, G.; Endo, Y. (Institut fur Pathologie der Universitat, Schonbeinstr. 40, CH-4056, Basel, Switzerland). *Klin. Wochenschr.* 55 (7):329-336; 1977.

In 64 hepatitis B surface antigen (HBsAg)-negative patients and 59 HBsAg-positive patients, serum anti-hepatitis B core antigen (HBcAg) levels were correlated with HBsAg in the cytoplasm and HBcAg and IgG in the nuclei of hepatocytes to determine the diagnostic and prognostic significance of these parameters. Two conditions were essential for the occurrence of nuclear IgG: (1) detectable HBcAg in the hepatocyte nuclei and (2) antibody formation to HBcAg with anti-HBcAg levels higher than 1:64. The 64 patients with various liver diseases who were negative for serum HBsAg were negative for all HBAg components in the liver tissue, and IgG was never observed in the liver cell nuclei. Anti-HBcAg antibodies were demonstrated in 5/64 patients with titers ranging from 1:32 to 1:512. HBcAg was present in liver cell nuclei in 17/19 patients with chronic aggressive hepatitis and 3/6 patients with hepatitis transitional between acute and chronic, all of whom were sera-positive for HBsAg. IgG nuclear fluorescence was observed in the hepatocytes of all but three of the patients with nuclear HBcAg, and serum anti-HBcAg titers were consistently elevated (1:512-1:4,096), regardless of presence of tissue HBcAg. Neither HBcAg nor IgG was observed in the hepatocytes of 19/20 patients with chronic nonaggressive hepatitis who were sera positive for HBsAg. These patients had cytoplasmic HBsAg in 16/19 biopsies and their anti-HBcAg titers ranged between 1:64 and 1:2,048. Nuclear IgG was demonstrated only in the presence of hepatocyte nuclear HBcAg and serum anti-HBcAg in eight kidney transplant patients on immunosuppressive medication who were HBsAg positive. It is concluded that immunofluorescent demonstration of IgG in liver cell nuclei strongly indicates a hepatitis B virus infection.

8356 PERIPHERAL IMMUNOFLUORESCENCE OF HEPATOCYTES: RELATION TO SMOOTH MUSCLE ANTIBODIES AND BILE CANALICULI. (Eng.) Diederichsen, H.; Riisom, K.; Andersen, I. (Odense Univ. Hosp., Odense, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85A(3): 399-404; 1977.

IgG immunofluorescence staining of the periphery of bovine hepatocytes was observed in sera from 50/52 cancer patients, 21/21 patients with acute viral hepatitis (hepatitis B surface antigen-positive), and 73/73 normal blood donors. The fluorescence reaction(s) with sera from the acute hepatitis patients were generally more intense than those with sera from the cancer patients and normal blood donors. The peripheral fluorescence reaction was not related to bile canaliculi, despite the fact that bile canaliculi antibody had been demonstrated in patients with chronic active liver disease. It also did not appear to be directed against contractile proteins on the liver cell membrane, since only a minor proportion of the sera had IgG smooth muscle antibody (SMA) and anti-actomyosin antibody obtained by affinity chromatography did not react with the hepatocyte. IgM immunofluorescence of the hepatocyte periphery was produced only with sera from patients with acute hepatitis, and the fluorescence pattern resembled that of IgG. All sera producing IgM peripheral fluorescence also showed IgM SMA. When rat liver hepatocytes were used instead of bovine hepatocytes, identical fluorescence patterns were obtained.

8357 HEPATITIS B CORE AND SURFACE ANTIGENS IN LIVER TISSUE: LIGHT AND ELECTRON MICROSCOPIC LOCALIZATION BY THE PEROXIDASE-LABELED ANTIBODY METHOD. (Eng.) Yamada, G.; Nakane, P. K. (Univ. Colorado Medical Center, 4200 E. 9th Ave., Denver, CO 80262). *Lab. Invest.* 36(6):649-659; 1977.

The ultrastructural and light microscopic localization of hepatitis B core antigen (HBcAg) and hepatitis B surface antigen (HBsAg) was studied in human liver tissues by the peroxidase-labeled antibody method. Several methods of fixation, staining, and inhibition of endogenous peroxidase activity were studied. The periodate-lysine-paraformaldehyde fixative effectively preserved the tissue structure and the antigenicity of both antigens, and the peroxidase-labeled Fab' fraction of IgG penetrated well into hepatocytes. HBcAg was present in nuclei, or cytoplasm of hepatic cells, or both. In nuclei, the antigen was found both in virus-like particles of approximately 20 nm diameter and in nuclear ground substance. In the cytoplasm, the antigen was found on membrane-bound ribosomes and free polysomes, and also in the ground substance of the cytosol near ribosomes and around nuclear membranes, especially near nuclear pores. HBcAg-positive virus-like particles were also demonstrated sparsely or in clusters in the cytoplasm. HBsAg was not present in nuclei, but was found in the perinuclear space and in cisternae of endoplasmic reticulum, and on nuclear, endoplasmic reticulum, and cell membranes of hepatic cells. HBsAg-positive 25- to 30-nm wide tubular forms, round particles (probably cross-sections of tubular forms), and a few large particles of 40 to 50 nm diameter were seen in cisternae. Such HBsAg-positive particles were also present in the intercellular space and in Disse's space. These findings suggest that HBcAg produced on the cytoplasmic ribosomes migrates through nuclear pores to the nucleus and is assembled into core particles there. These particles may then move through nuclear pores to the cytoplasm where they are invested with HBsAg-positive membrane in cisternae of endoplasmic reticulum or as they enter the endoplasmic reticulum. These virus particles are then released together with other HBsAg-positive forms into the intercellular space by reversed phagocytosis.

8358 PRESENCE OF HBcAg, DNA POLYMERASE ACTIVITY, DANE PARTICLE IN DIFFERENT CATEGORIES OF HBsAg CARRIERS AND EVIDENCE OF HEPATITIS TYPE B INFECTION IN THEIR FAMILY CONTACTS. (Eng.) Zanetti, A. R.; Ferroni, P. (Istituto di Virologia dell'Universita di Milano, Via Pascal, 38-20133 Milano, Italy). *Boll. Ist. Sieroter. Milan.* 56(1):79-86; 1977.

Dane particles, DNA polymerase activity, and the e system were investigated in 15 hepatitis B surface antigen (HBsAg) carriers on hemodialysis and in 28 asymptomatic HBsAg-positive blood donors. A correlation between the presence in the sera of these markers and signs of hepatitis type B infection in family contacts was studied. The e antigen (HBeAg) was present in 10 of the 15 hemodialysis patients but in none of the healthy carriers. Among dialysis patients, a perfect correlation between Dane particles, DNA polymerase activity, and HBeAg was found. In contrast, antibody to HBeAg (anti-HBe) was detected in 15 of the 28 asymptomatic carriers and in none of renal patients. No association between anti-HBe and DNA polymerase activity or Dane particles could be found. Two asymptomatic carriers had DNA polymerase activity and Dane particles in the serum but were HBeAg negative. The difference in the prevalence of HBsAg in family clusters of hemodialysis patients and of blood donors compared with healthy controls was statistically significant ($p<0.01$, $p<0.05$). In addition, the highest incidence of serological evidence of hepatitis B virus (HBV) infection occurred in the relatives of dialysis patients; the lowest occurred in the household contacts of asymptomatic HBsAg carriers. These findings support the association between the presence of Dane particles, DNA polymerase activity, or HBeAg and risk of HBV infection.

8359 CLINICAL AND IMMUNOLOGICAL STUDIES ON HEALTHY BLOOD DONORS: HEPATITIS B ANTIBODY CARRIERS. (Eng.) Cianciara, J.; Swiderska, H.; Slusarczyk, J.; Loch, T. (Medical Acad., ul. Wolska 37, 01-201 Warsaw, Poland). *Vox Sang.* 33 (2):88-92; 1977.

The immune status of 10 healthy blood donors persistently seropositive for antibody to hepatitis B surface antigen (anti-HBs) and without a history of clinically overt viral hepatitis was studied. While physical examination and biochemical liver function tests exhibited normal values in all cases, immunologic studies revealed coexistence of a long-term anti-HBs carrier state with the presence of cell-mediated immunity to hepatitis B virus antigens and autoantibodies in some; antinuclear antibodies occurred in six cases, and smooth muscle antibodies occurred in five. These results suggest a complex immunologic phenomenon underlying the development of the anti-HBs carrier state.

8360 TRANSMISSION OF HEPATITIS B TO CHIMPANZEES BY HEPATITIS B SURFACE ANTIGEN-POSITIVE SALIVA AND SEMEN. (Eng.) Alter, H. J.; Purcell, R. H.; Gerin, J. L.; London, W. T.; Kaplan, P. M.; McAuliffe, V. J.; *et al.* (Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD 20014). *Infect. Immun.* 16(3):928-933; 1977.

To assess the infectivity of hepatitis B surface antigen (HBsAg)-containing body fluids other than blood, chimpanzees were inoculated i.v. with saliva and semen obtained from four HBsAg-positive humans implicated in non-percutaneous transmission of hepatitis B. Saliva and semen samples were negative for occult blood. The titer of HBsAg in saliva was on the average only 1/3,000 that of the corresponding serum. One chimpanzee, inoculated sequentially with saliva from three individuals, developed HBsAg at 9 weeks and serum glutamic pyruvic transaminase elevation at 13 weeks after injection. HBsAg persisted for 15 weeks. This animal also developed antigen, anti-core antibody, and anti-surface antibody. Liver biopsies showed acute hepatitis that subsequently resolved. A second chimpanzee, inoculated with HBsAg-positive semen, developed HBsAg and elevated serum glutamic pyruvic transaminase 4 weeks after inoculation and then died suddenly without explanation. HBsAg was positive in two consecutive samples and was confirmed by specific neutralization. Autopsy did not reveal evidence of hepatitis. The results indicate that HBsAg-positive saliva and, probably, semen contain infectious virus and suggests that saliva and/or semen may serve as important mechanisms in the transmission of type B hepatitis.

8361 AMERICAN STUDIES HAVE ESTABLISHED THE FACT THAT THE BLOOD OF COMMERCIAL DONORS CARRIES A HIGH RISK OF TRANSMITTING HEPATITIS, WHEREAS BLOOD FORM VOLUNTARY DONORS CARRIES A LOW RISK ONLY. HAS THE SCREENING OF PLASMA FOR THE ABSENCE OF HEPATITIS-B-ANTIGEN AFFECTED THE DIFFERENCE BETWEEN THE TWO DONOR GROUPS TO ANY SIGNIFICANT DEGREE? (Eng.) Ashworth, J. N.; Bayer, W. L.; Mosley, J. W. LIVER AND BILIARY TRACT

Chronic Hepatitis

8381 HLA AND CHRONIC ACTIVE HEPATITIS (CAH). (Eng.) Dumble, L. J.; Mackay, I. R. (Royal Melbourne Hosp., Univ. Melbourne, Melbourne, 3052 Victoria, Australia). *Digestion* 15(4):254-259; 1977.

Mixed lymphocyte culture (MLC) studies were performed on lymphocytes from the family of a patient with chronic active hepatitis (CAH) after it was observed that the patient and her four siblings were histocompatibility antigen (HL) A and B identical. The paternal haplotype transmitted was HLA-A3, B7, and the maternal haplotype was HLA-A1, B8, so that of the children was HLA-A1, A3, B7, B8. A strong but not absolute association has previously been demonstrated between classic CAH and HLA-B8. In the MLC study, the patient's lymphocytes both stimulated and responded to the lymphocytes of her four healthy siblings; the lymphocytes of the siblings were mutually unresponsive. It is suggested that the patient had inherited a lymphocyte-defined antigen not expressed in the cells of her four siblings, which would explain the absence of disease in the other children.

8382 CHRONIC AGGRESSIVE HEPATITIS WITH NORMAL AND ELEVATED COMPLEMENT LEVEL IN THE BLOOD. (Spa.) Diaz-Rubio Garcia, M.; Enriquez, L.; Diaz-Rubio Garcia, E. (Catedra de Patologia y Clinica Medica, Universidad Complutense, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 50(1): 31-36; 1977.

Among 28 patients with chronic aggressive hepatitis, 15 patients were hypocomplementemic (group 1) and 13 patients had normal levels of complement in the blood (group 2). These groups were compared with respect to the complement components C3, CT and C4, albumin, SGOT, prothrombin, IgG, IgA, IgM, and the hepatitis B surface antigen (HBsAg). Group 1 had significantly lower blood levels of C3, prothrombin ($p<0.001$), and CT ($p<0.05$). IgA levels in group 1 were higher than in group 2 ($p<0.05$). Positive HBsAg indications were found in 5/15 group 1 and 3/13 group 2 patients. The Waaler-Rose test (the sheep cell agglutination test) was positive in 33% of group 1 patients and 7.7% of group 2 patients; these results were not statistically significant. Significant differences ($p<0.025$) were detected by the latex agglutination test; negative reactions were recorded for group 1 (20%) and group 2 (61.6%), positive reactions for group 1 (26.6%) and group 2 (30.7%), and strongly positive reactions for group 1 (53.4%) and group 2 (7.7%). From these observations it was not possible to conclude that hypocomplementemia proceeds or does not proceed from a defect in hepatic synthesis; a study of increased catabolism is proposed. The possible role of circulating immune complexes in depleting complement in patients with chronic aggressive hepatitis is discussed.

8383 LYMPHOCYTE SUBPOPULATIONS IN CHRONIC LIVER DISEASE. (Ita.) Fargion, S. R.; Cappellini, M. D.; Malesci, A.; Ronchi, G.; Fiorelli, G. (Istituto di Clinica Medica II dell'Universita di Milano, Milan, Italy). *Minerva Gastroenterol.* 22(3):245-250; 1976.

T and B lymphocyte populations and cellular immune reactions were determined in patients with chronic liver disease to evaluate whether there is an alteration of lymphocyte subpopulations in this disease. One group of patients with chronic persistent hepatitis (CPH), chronic active hepatitis (CAH), or primary biliary cirrhosis (PBC) had received no immunosuppressive therapy. A second group of patients with CAH had received either prednisone or azathioprine for periods from 6 months to 2 yr. Antinuclear, antimitochondrial, antismooth muscle (SMA), antigastroparietal, antiliver/kidney, and antithyroid antibodies were determined by immunofluorescence. Lymphocyte transformation by phytohemagglutinin (PHA) or pokeweed mitogen (PWM) was determined by tritiated thymidine incorporation. Plasma cells in liver tissue were also determined. SMA levels were elevated in CAH patients and were highest in those patients who were serum positive for the presence of hepatitis B surface antigen. Lymphocyte transformation by PHA and PWM was significantly reduced in CAH patients but was unaffected in CPH patients. In CPH and CAH patients there was no difference in the ratio of T and B lymphocytes with respect to the controls. In PBC patients, there was a slight increase in the number of peripheral B cells. Immunosuppressive therapy did not alter the number of circulating T and B cells, whereas liver plasma cells were reduced by azathioprine treatment.

8384 TREATMENT OF CHRONIC ACTIVE HEPATITIS WITH EITHER PREDNISOLONE OR CORTICOTROPHIN: A CONTROLLED TRIAL. (Eng.) Giusti, G.; Piccinino, F.; Ruggiero, G.; Galanti, B.; Lucchelli, P. E.; Manzillo, G.; *et al.* (Clinica delle Malattie Infettive 1, Facolta di Medicina, Via D. Cotugno 1 presso Osp. Gesu e Maria, I-80 135 Napoli, Italy). *Acta Hepatogastroenterol.* 24(3):131-139; 1977.

The effect of prednisolone was compared with that of synthetic corticotrophin in the treatment of 54 patients with chronic active hepatitis. Twenty-nine patients were treated with prednisolone (maintenance dose 15 mg/day), and 25 were treated with depot synthetic corticotrophin (maintenance dose 1 mg/week, i.m.); all were followed up for 6-24 months or longer. In this series, young men predominated, the incidence of serum hepatitis B surface antigen (HBsAg) positivity approached 80% in both treatment groups, and no patient had initial evidence of cirrhosis or had autoimmune-associated diseases. With either drug, the SGOT levels decreased during the initial 12 months of therapy ($p<0.05$); initial jaundice, when present, had disappeared by the third month of treatment. With both treatments, globulins and γ-globulins decreased significantly after 12-24 months of therapy. Serum HBsAg persisted in all but two cases. Serial liver biopsies showed the following evolutions of histological activity: 12 cases (22%) improved to the "inactive phase" (8 with prednisolone and 4 with corticotrophin); 19 (35%) improved to a lesser extent (8 with prednisolone and 11 with corticotrophin); 17 (32%) remained unchanged (11 with prednisolone and 6 with corticotrophin); and 6 (11%) worsened (2 with prednisolone and 4 with corticotrophin). Morphological features of cirrhosis developed in 15 patients (8 treated with prednisolone and 7 with corticotrophin). In seven of these patients, the morphological picture was associated with an improvement in inflammatory activity, and none of the 15 patients developed symptoms of cirrhosis. Differences between treatments were not significant. Side-effects necessitating drug discontinuation occurred only in six cases. The data suggest that both treatments result in improvement in chronic active hepatitis.

8385 EFFECT OF CORTICOSTEROID TREATMENT ON BILIRUBIN METABOLISM IN CHRONIC AGGRESSIVE HEPATITIS. (Eng.) Kawasaki, H.; Ogata, T.; Irisa, T.; Hirayama, C. (Tottori Univ. Medicine, Yonago 683, Japan). *Acta Hepatogastroenterol.* 24(3):175-181; 1977.

Unconjugated bilirubin metabolism was studied in the plasma of 17 patients with chronic hepatitis and 7 normal subjects, and the effect of corticosteroid treatment on bilirubin metabolism was investigated. Hepatic uptake, reflux from the liver to the plasma, and hepatic conjugation were calculated by two-compartmental analysis from the plasma disappearance curves of unconjugated bilirubin following a single i.v. injection of bilirubin (2 mg/kg). The clearance remained within normal range in patients with chronic persistent hepatitis, but was significantly impaired in 12 patients with chronic aggressive hepatitis, in whom corticosteroid treatment improved the clearance significantly ($p<0.01$). Since urinary excretion of d-glucaric acid remained unchanged by corticosteroid treatment, the improved clearance may be attributable to increased hepatic parenchymal function.

8386 THE PROGNOSIS OF CHRONIC AGGRESSIVE HEPATITIS: A CLINICAL AND MORPHOLOGICAL FOLLOW-UP STUDY. (Eng.) Dietrichson, O.; Christoffersen, P. (Hvidovre Hosp., DK-2650 Hvidovre, Denmark). *Scand. J. Gastroenterol.* 12(3):289-295; 1977.

To study the prognosis of chronic aggressive hepatitis (CAH), 85 patients were followed up; repeat liver biopsies and/or autopsy liver sections were available in 74 cases. The median time of observation was 45 months. Cirrhosis was demonstrated in 38 patients, and cirrhosis was suspected in a further 5 patients. Fifteen patients showed convincing histological improvement, and the remaining 16 still had chronic hepatitis. Twenty-six patients died during the observation period, seven of these of liver failure after the development of cirrhosis. The clinical follow-up of the 59 survivors (median observation time 69 months) showed biochemically active liver disease in 11 cases, all having cirrhosis or chronic aggressive hepatitis in the last biopsy. The clinical findings were correlated with the morphological follow-up diagnosis and the immunosuppressive treatment. Comparison of the initial histological, clinical, and serological variables was made in two well-defined follow-up groups. There were more women; marked portal inflammation, abnormal bile duct epithelium, and circulating autoantibodies occurred more frequently in the group with later development of cirrhosis than among the patients with subsequent morphological improvement. The results suggest candidates for thorough follow-up and more intensive immunosuppressive or other treatment.

8387 FUNCTIONAL ACTIVITY OF LEUKOCYTES IN PATIENTS WITH CHRONIC HEPATITIS AND LIVER CIRRHOSIS DURING PREDNISOLONE TREATMENT. (Rus.) Veprinskaya, S. I.; Radugina, G. S. (Donetsk Medical Inst., Donetsk, USSR). *Vrach. Delo* (6):98-100; 1977.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

8389 HEPATIC SIDEROSIS AND ALCOHOLISM. (Ita.) Schmid, C.; Giordano, F. (Servizio di Anatomia e Istologia Patologica dell'Ente Ospedaliero di Vimercate e Ornago, Italy). *Pathologica* 69(987/988):23-34; 1977.

The cellular distribution of iron deposits was evaluated in 329 liver biopsy specimens from patients with a normal liver or with various liver diseases. Mild, moderate, or severe hepatic siderosis was present in 174 cases. In 14.4% of the cases, iron deposits were present in the parenchymal cells. In 20.1% of the cases, iron was contained within the Kupffer cells, while in most cases (65.5%), the iron deposits were both histiocytic and parenchymal. The deposits in the parenchymal cells were generally granular extending over a surface of 2 μm, while those in the Kupffer cells were under 0.5 μm. Siderosis was present in 67.1% of the cases of liver steatosis, in 39.5% of tha cases of liver cirrhosis, and in 77.5% of the cases of alcoholic liver disease.

8390 RED CELL METABOLIC AND MEMBRANE FEATURES IN HAEMOLYTIC ANAEMIA OF ALCOHOLIC LIVER DISEASE (ZIEVE'S SYNDROME). (Eng.) Goebel, K. M.; Goebel, F. D.; Schubotz, R.; Schneider, J. (Medizinische Poliklinik, Univ. Marburg, Marburg/Lahn, W. Germany). *Br. J. Haematol.* 35(4):573-585; 1977.

Zieve's syndrome (ZS, transient hemolytic anemia, jaundice, hyperlipoproteinemia, and alcohol-induced liver disease) was studied in 20 men during the acute phase, and in 10 men during the remittent phase. Ten chronic alcoholics without hemolysis and 10 healthy men served as controls. RBC were separated into old and young cells by density-layer centrifugation. Those fractions containing older RBC disclosed a pyruvate-kinase instability that resulted in impaired metabolism. Changes in membrane lipid composition, as indicated by increased cholesterol and polyunsaturated fatty acids (PUFA), were also detected in patients during the acute phase of ZS. Alcohol-induced RBC vitamin-E deficiency with a decrease in PUFA levels may provoke an oxidation of reduced RBC glutathione, which in turn results in the enzyme instability. This study supports the hypothesis that the putative role of the RBC metabolic injury in the origin of hemolysis in ZS cannot be envisaged without introducing membrane-linked and extracellular cofactors.

8391 COBALT-ACTIVATED ACYLASE ACTIVITY AND IMMUNOGLOBULIN LEVEL IN BLOOD SERUM OF CHRONIC ALCOHOLICS. (Pol.) Kryszewski, A.; Bardzik, I.; Przezdziak, J. (I Klinika Chorob Wewnetrznych Instytutu Chorob Wewnetrznych AM, ul. Debinki 7, 80-211 Gdansk, Poland). *Pol. Tyg. Lek.* 32(15):561-564; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

8396 AETIOLOGY OF CIRRHOSIS, HEPATIC FIBROSIS, AND HEPATOCELLULAR CARCINOMA. (Eng.) Blenkinsopp, W. K.; Haffenden, G. P. (St. Mary's Hosp., London W2, England). *J. Clin. Pathol.* 30(6): 579-584; 1977.

Autopsy specimens were examined to investigate the contribution of histology to the diagnosis of the etiology of cirrhosis, hepatic fibrosis, and hepatocellular carcinoma. The histological study of 69 cases of cirrhosis, 9 of severe generalized hepatic fibrosis, and 19 of hepatocellular carcinoma showed an association with alcohol, hepatitis B surface antigen (HBsAg), or α_1-antitrypsin bodies in 41 (cirrhosis), 5 (fibrosis), and 9 (carcinoma) cases, resp. Eight cases of cirrhosis and two of carcinoma had double associations, HBsAg being present in all. Orcein and aldehyde fuchsin staining gave both false-positive and false-negative results when compared with immunofluorescence and immunoperoxidase methods for HBsAg. Large amounts of copper were found in four cirrhotic livers, and moderate amounts in 13; the diagnostic value of copper staining is questioned.

8397 LIVER CIRRHOSIS AS CONSEQUENCE OF GENETIC DEFECTS.

(Ger.) Morl, M.; Gabriel, L. (Stoffwechselklinik der LVA Wurttemberg, D-6990 Bad Mergentheim, W. Germany). *Med. Klin.* 72(12):483-491; 1977.

Observations and studies on liver cirrhosis due to Wilson's disease and idiopathic hemochromatosis are reviewed. Wilson's disease, basically a defect of copper incorporation into ceruloplasmin, leads to excessive copper storage in the liver, fatty degeneration, periportal fibrosis, chronic hepatitis, and ultimately to liver cirrhosis after a usually clinically silent latent period of several years. Long-term normalization of copper storage can be achieved by liver transplantation, but not by substitution of human ceruloplasmin. Wilson's disease is usually manifested as acute or chronic hepatopathy, mostly mimicking infectious hepatitis, or juvenile cirrhosis. The complications include hemolytic anemia, fulminant hepatitis, hepatic coma, and esophageal varices. Life-long therapy with D-penicillamine (0.6-1.2 g) and vitamin B_6 is recommended, even in presymptomatic cases. Excessive iron storage in the liver in idiopathic hemochromatosis over several years to decades leads to liver cirrhosis. Complications include esophageal varices, hepatic coma, hepatocellular carcinoma, and diabetes mellitus. It is possible to achieve a 5-yr survival rate of nearly 90% by regular bloodlettings.

8398 BILE SALTS SECRETION IN CIRRHOSIS.

(Eng.) Correia, J. P.; Areias, E.; Meneses, L.; Tiago, E. (Hosp. Escolar Sta. Maria, Lisbon 4, Portugal). *Acta Hepatogastroenterol. (Stuttg.)* 24(1):15-19; 1977.

Basal and stimulated bile salt secretion was studied in 10 normal subjects (controls) and in 16 patients with alcoholic cirrhosis to investigate factors that could interfere with fat absorption. In the controls, the total bile salt concentration was 2.93 ± 2.15 µmol/ml during the basal period and 2.88 ± 2.58 µmol/ml 60 min after stimulation by secretin (1 U/kg i.v.). In the cirrhosis patients, the values were 4.83 ± 2.74 and 1.96 ± 1.25 µmol/ml, resp. The differences between the two groups were not significant. During the first 20 min after secretin, however, the total bile salt concentration was >3 µmol/ml in 8/10 controls (mean, 6.26 ± 5.03 µmol/ml) and <2 µmol/ml in 10/16 patients (mean, 3.16 ± 2.12 µmol/ml). The ratios of trihydroxy to dihydroxy bile salts were similar in both groups. The ration between bile salts conjugated with glycine and those conjugated with taurine was 1.69 ± 1.30 in the controls and 1.02 ± 0.65 in the cirrhotics. This difference was statistically significant ($p<0.05$). However, the ratio of free to conjugated bile salts was higher in the cirrhotics (0.42 ± 0.9, versus 0.17 ± 0.14 in controls). The lower concentration of total bile salts immediately after secretin and the higher proportion of taurine conjugates and of free bile salts may be relevant to the altered fat digestion and absorption and bowel motility found in alcoholic cirrhosis patients.

8399 STUDIES ON THE KINETICS OF UNCONJUGATED $[^{14}C]$BILIRUBIN METABOLISM IN NORMAL SUBJECTS AND PATIENTS WITH COMPENSATED CIRRHOSIS.

(Eng.) Owens, D.; Jones, E. A.; Carson, E. R. (Walton Hosp., Rice Lane, Liverpool L9 1AE, England). *Clin. Sci. Mol. Med.* 52(6):555-570; 1977.

The kinetics of unconjugated $[^{14}C]$-bilirubin metabolism were studied and analyzed in terms of a three-pool model in seven normal subjects and eight cirrhotic patients who did not have an appreciable degree of conjugated hyperbilirubinemia. The mean volume of distribution, the mean mass of the rapidly mixing pool ("plasma"--pool 1), and the mean 4-hr retention were greater than the corresponding values in the normal subjects (81.7 ± 11.2 versus 68.1 ± 12.5 ml/kg body weight, 69.1 ± 43.8 versus 30.6 ± 8.9 µmol, $p<0.05$, and 18.6 ± 6.6 versus 10.6 ± 3.4%, $p<0.01$, resp.). In contrast, the mean fractional clearance rate and the mean estimated erythrocyte life-span were significantly less than the corresponding values in normal subjects (0.0059 ± 0.0019 versus 0.0086 ± 0.0025/min, $p<0.01$ and 93.6 ± 40.9 versus 129.3 ± 6.3 days, resp.). Mean hepatic clearance rate and mean bilirubin production rate were not significantly different than those in normal subjects. Of the model-dependent parameters of unconjugated $[^{14}C]$-bilirubin metabolism, the mean fractional transfer rates and fluxes from pool 1 to pool 3 ("extravascular") and vice versa were significantly greater than the corresponding values in the normal subjects ($p<0.05$). The mean fractional transfer rate from pool 1 to pool 2 ("hepatic unconjugated bilirubin") was less than that in normal subjects and from pool 2 to the conjugated pool was greater than that in normal subjects ($p>0.05$). It is suggested that in compensated cirrhotics the efficiency of the liver in extracting unconjugated bilirubin from plasma against a concentration gradient is impaired, even though the liver's capacity to conjugate bilirubin may be normal. As a result of the increased volume of distribution, the absolute hepatic clearance of unconjugated bilirubin is relatively well maintained.

8400 HEME CATABOLISM IN LIVER CIRRHOSIS WITH PORTAL HYPERTENSION AFTER SHUNT SURGERY.

(Eng.) Mercke, C.; Lundh, B.; Bengmark, S.; Borjesson, B.; Simert, G.; Vang, J. (Univ. Hosp., S-221 85 Lund, Sweden). *Scand. J. Gastroenterol.* 12(4):473-480; 1977.

Endogenous production of carbon monoxide (VCO) and total and direct-reacting serum bilirubin (TSB, DRB) were determined in 26 patients with liver cirrhosis and portal hypertension to evaluate the effect of various shunt operations on total heme catabolism. The patients were divided into three groups. In group I, 11 nonoperated patients had a mean VCO of 18.4 ± 6.0 μmol/mmol total body heme per day (reference value 12.6 ± 2.9). In group II, seven patients who underwent subcutaneous transposition and a subtotal splenectomy had a mean VCO that was not significantly raised (14.4 ± 4.7 μmol/mmol/day). In group III, eight patients underwent a modified distal splenorenal shunt; the highest mean VCO (26.1 ± 9.0 μmol/mmol/day). The mean TSB in the three groups was 34.8 ± 29.2, 11.2 ± 3.0, and 46.4 ± 41.0 μM, resp., and mean DRB was 18.2 ± 20.8, 3.7 ± 1.0, and 26.8 ± 34.1 μM, resp. Estimated from preoperative laboratory values, there was no difference in liver function between the three groups. Heme catabolism is increased by 50% in liver cirrhosis complicated by portal hypertension, probably due to a slight decrease in erythrocyte survival. Heme catabolism tends to normalize after subcutaneous transposition and subtotal splenectomy. After spleno-renal shunting, a further increase in heme catabolism is seen. The increase in serum bilirubin often seen after the latter type of surgery is mainly related to a raised bilirubin production and not to a further decrease in liver function.

8401 STUDY OF PANCREATIC RESPONSE TO SECRETIN-PANCREOZYMIN IN CIRRHOTIC PATIENTS. COMPARATIVE ANALYSIS BY FECAL CHYMOTRYPSIN TEST. (Spa.) Aparisi-Quereda, L.; Rodrigo Gomez, J. M.; Garcia Perez, H.; Guix-Garcia, J.; Serra-Desfilis, M. A.; Olmo-Puchalt, J. A.; Wassell, A. (Catedra de Patologia y Clinica Medica "B," Facultad de Medicina, Valencia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(6):803-805; 1976.

Pancreatic function in 21 patients with hepatic cirrhosis of diverse etiology was compared with that in 18 normal controls. The pancreatic function was tested with a stimulus of secretin (1 U/kg) and pancreozymin (2 U/kg); feces were collected during 3 days of administration of the Schmidt diet and during another 3 days of an experimental meal. The cirrhotic patients segregated a larger volume of pancreatic juice (279 cm^3/hr versus 201 cm^3/hr, $p<0.05$), with smaller concentrations of bicarbonate (81 ± 16 mEq/l versus 90 ± 18 mEq/l, $p<0.05$), lipase (855 ± 536 U/cm^3/hr versus 1,217 ± 352 U/cm^3, $p<0.02$), and chymotrypsin (144 ± 67 U/cm^3 versus 194 ± 79 U/cm^3, $p<0.05$) than controls. The cirrhotic patients also had higher values for fecal fats (4.5 ± 3.7 g/day versus 2.4 ± 1.4 g/day, $p<0.025$) and proteins (10.9 ± 5.5 g/day versus 7.9 ± 3.8 g/day, $p<0.05$) than controls. The concentration of fecal chymotrypsin was slightly lower in the cirrhotic patients than in controls (113 ± 51 U/g feces versus 128 ± 78 U/g feces). The experimental meal induced a smaller increase in the fecal chymotrypsin in cirrhotic patients (from 13.4 ± 8.1 KU/day after the Schmidt diet to 19.1 ± 20.2 KU/day after the experimental meal) than in normal controls (from 12.7 ± 12 KU/day, Schmidt diet, to 21.8 ± 21.5 KU/day, experimental meal). These results do not support the existence of a pancreatic insufficiency intense enough to justify the appearance of "esteotorrea" and creatinuria.

8402 NEW TECHNIQUES FOR INTERRUPTION OF GASTROESOPHAGEAL VENOUS BLOOD FLOW. (Eng.) Pereiras, R.; Viamonte, M., Jr.; Russell, E.; LePage, J.; White, P.; Hutson, D. (Veterans Admin. Hosp., Miami, FL). *Radiology* 124(2):313-323; 1977.

Enlarged gastroesophageal veins were successfully obliterated in 41 patients with hepatic cirrhosis and portal hypertension using embolization with modified autogenous clots and/or Gelfoam, balloon occlusion, iatrogenic perivenous hematoma, sclerosing agents (Sotradecol and Keflin), or a combination of these methods. Surgical exploration of 16 patients and autopsies of 5 showed persistent obliteration ranging between 3 weeks and 7 months. No major complications requiring reparative surgery were encountered. Gelfoam soaked with Sotradecol is the preferred agent because it provides persistent obliteration of the embolized veins. Patients who are acutely bleeding or have done so previously are candidates for selective obliteration of the gastroesophageal veins.

8403 PREGNANCY IN CIRRHOTIC AND NONCIRRHOTIC PORTAL HYPERTENSION. (Eng.) Varma, R. R.; Michelsohn, N. H.; Borkowf, H. I.; Lewis, J. D. (Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI 53226). *Obstet. Gynecol.* 59(2):217-222; 1977.

The course of pregnancy in one patient with chronic active hepatitis (CAH) and cirrhosis, and in another with extrahepatic portal vein obstruction (EHPVO) is described. The management of pregnancy in these diseases associated with portal hypertension is discussed, and risks of pregnancy are compared. The patient with CAH, a 25-yr-old woman, presented with anovulatory cycles, and ovulation occurred following immunosuppressive therapy. The second patient, a 21-yr-old woman, had experienced episodes of gastrointestinal bleeding since age 5 and presented with severe bleeding at 32 weeks gestation. Both women experienced massive upper gastrointestinal bleeding from esophageal varices. Bleeding was difficult to control and required variceal ligation in the first patient. Both patients manifested features suggesting cerebral edema, indicating the need for caution with fluid and electrolyte therapy. Recovery of the woman with CAH after a low cervical cesarean delivery was slow. In the second patient, spontaneous labor of a stillborn fetus occurred 2 days after an emergency transesophageal variceal ligation was performed. A review of the literature demonstrated that variceal bleeding occurred in 43% of women with EHPVO, compared to 23% of those with CAH and cirrhosis. Additional complications, including hepatocellular failure (24%), occurred in patients with CAH, but not in EHPVO.

8404 STUDY OF 32 PATIENTS TREATED BY PORTA-SYSTEMIC SHUNTS AT THE HOSPITAL CENTER OF LAVAL UNIVERSITY OVER A 5-YEAR PERIOD. (Fre.) Painvin, G. A.; Martineau, G. (Centre Hospitalier de l'Universite Laval, Monteal, Quebec, Canada). *Union Med. Canada* 106(3):347-351; 1977.

Gallbladder and Biliary Tract Diseases

8419 THE EFFECT OF PARA-AMINOBENZOIC ACID AND TAUROCHOLIC ACID FEEDING ON HUMAN BILE COMPOSITION. (Eng.) Gardner, B.; Dennis, C.; Patti, J.; Chenouda, M. (Downstate Medical Center, Brooklyn, NY). *Surg. Gynecol. Obstet.* 144(6):879-882; 1977.

Seven patients were investigated after cholecystectomy and exploration of the common bile duct to determine bile composition and excretion rates. An initial depression of the major components of bile stabilized by the sixth postoperative day. Feeding of para-aminobenzoic acid (2 g 3 times/day, 2 days) and taurocholic acid (3 g on 1 day) to these patients resulted in an increase in excretion of total bile acids, taurine, and glycine conjugates, cholates, and deoxycholates. Para-aminobenzoic acid failed to block glycine conjugation. Preferential conjugation of bile acid with glycine is due to a deficient taurine pool and not to a preferential metabolic pathway.

8420 LIMY BILE. (Ger.) Schierholt, K. D. (Rontgenabteilung, Krankenhauses St. Josef, 6220 Rudesheim, W. Germany). *Fortschr. Roentgenstr.* 127(1):26-29; 1977.

The roentgenological, clinical, and biochemical aspects of limy bile are reviewed on the basis of a survey of 43 cases that occurred during 1937-1969. In the absence of characteristic clinical symptoms, radiological investigation is essential for diagnosis. On x-ray, the gallbladder appears as a dense shadow containing several round, annular-shaped shadows. It is of normal or slightly reduced size, and it usually shows mild inflammation with occlusion of the cystic duct by a cholesterol stone. The gallbladder contains greenish white limy bile produced by the bladder mucosa. The limy bile contains 24-52% calcium carbonate in amorphous and crystalline form, 12-55% cholesterol, and a small quantity of calcium phosphate. Bile pigments are present in trace amounts, if at all. Although the calcium carbonate may reach a pulpy consistency, it never forms solid stones. The blood calcium level was determined in four patients, and it was normal. The few clinical symptoms include attacks of biliary colic that usually recur at long intervals. Jaundice is rare, and some patients were symptom-free. The observations indicate that limy bile is not an early stage of gallstone formation and that it does not result from calcified gallbladder empyema. Limy bile formation must occur parallel to the formation of calcium carbonate stones.

8421 CONGENITAL EXTRAHEPATIC BILIARY ATRESIA. (Eng.) Scotto, J. M.; Stralin, H. G. (Hopital de Bicetre, U 56 INSERM, 94270 Le Kremlin-Bicetre, France). *Arch. Pathol. Lab. Med.* 101(8):416-419; 1977.

Ten cases of congenital extrahepatic biliary atresia were studied ultrastructurally. Liver samples were obtained from each patient, fibrous tracts were also secured in six patients. Extrahepatic biliary ducts occurred in the fibrous tracts, but were hypoplastic. In places, necrosed epithelial cells, without obvious inflammatory processes, were observed. The ductular cell cytoplasmic changes and the inflammatory reaction are different according to whether extrahepatic or intrahepatic sites are considered. These differences, as well as the cytoplasmic modifications of liver parenchymal cells, seem to be the result of impaired bile flow. On the other hand, extrahepatic bile duct hypoplasia and necrosis seem to be directly related to the unknown origin of this disease. If the nuclear changes of hepatocytes are the expression of direct injury to the liver, it is possible that the disease might evolve as an independent liver disease, despite a correctly performed and uncomplicated surgical intervention.

8422 PRIMARY SCLEROSING CHOLANGITIS. (Ita.) Lamarca, S.; Farinella, M. (Ospedale Civile di Castellamonte, Castellamonte, Italy). *Arch. Sci. Med. (Torino)* 134(2):219-223; 1977.

A case of intermittant icterus in a male patient was observed over a 2-yr period without a definitive laboratory or clinical diagnosis. Hepatic-cholestatic fibrosis with stenosis of the lumen and patency of Vater's tubule was diagnosed by laparotomy. Bile duct drainage was accomplished by insertion of a transcholedochal, transpapillary T-tube that was left in place for 4 months. Twenty months after removal of the tube, the patient is in good health with no recurrence of icterus. The final diagnosis was primary sclerosing cholangitis.

8423 CHOLECYSTOKININ CHOLECYSTOGRAPHY IN THE DIAGNOSIS OF CHRONIC ACALCULOUS CHOLECYSTITIS AND BILIARY DYSKINESIA: A CRITICAL APPRAISAL. (Eng.) Berk, R. N. (5323 Harry Hines Blvd., Dallas, TX 75235). *Gastrointest. Radiol.* 1(4):325-330; 1977.

The active fragment of the cholecystokinin molecule has been made available for use in clinical practice; reports on the value of cholecystokinin cholecystography were, therefore, reevaluated to determine whether the procedure is worthwhile in patients with persistent symptoms and a normal conventional oral cholecystogram. A literature review discloses that there is no uniform agreement on what constitutes an abnormal examination and raises serious questions concerning the scientific validity of much of the data. It is apparent that there is no immutable evidence indicating that cholecystokinin cholecystography is an accurate technique to determine which patients in this category will benefit from cholecystectomy.

8424 CHOLEDOCHOSCOPY IN EXPLORATION OF THE COMMON BILE DUCT. (Eng.) Finnis, D.; Rowntree, T. (Dept. Surgery, Univ. British Columbia, Vancouver, British Columbia, Canada). *Br. J. Surg.* 64(9):661-664; 1977.

The technique of operative fiberoptic choledochoscopy was evaluated in 88 patients with gallstones requiring exploration of the common bile duct. There were no cases of retained calculi that were endoscopically undetected. Postoperative T-tube cholangiography was carried out in 81 cases; this technique confirmed the findings of operative biliary endoscopy in all cases. Choledochoscopy is an accurate and safe operative procedure that can eliminate the problem of undetected residual calculi.

8425 TREATMENT OF RETAINED BILE DUCT CALCULI WITH T-TUBE INFUSION OF SODIUM CHOLATE AND HEPARIN. (Eng.) Christiansen, L. A.; Schersten, T.; Burcharth, F.; Bruusgaard, A.; Lindblad, L.; Cahlin, E. (Rigshospitalet, Univ. Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(3):337-339; 1977.

The value of sodium cholate and heparin infusion through the T-tube in the treatment of retained radiolucent bile duct calculi was studied in 26 patients in whom the presence of bile duct calculi was diagnosed by postoperative cholangiography. All patients received an infusion of 15-20 g sodium cholate in 1,000 ml saline and 20,000 U of heparin in 1,000 ml saline every 24 hr. The calculi disappeared in 19 of 26 patients. No complications were encountered. This treatment is recommended prior to reoperation in all patients with retained radiolucent bile duct calculi diagnosed by postoperative cholangiography through the T-tube.

8426 THE CRYSTALLINE SALTS OF CALCIUM BILIRUBINATE IN HUMAN GALLSTONES. (Eng.) Sutor, D. J.; Wilkie, L. I. (Univ. Coll. Hosp. Medical Sch., Rayne Inst., 5 University St., London WC1E 6JJ, England). *Clin. Sci. Mol. Med.* 53(1):101-103; 1977.

To determine whether the crystalline pigment of gallstones is calcium bilirubinate, the acid, neutral, and "intermediate" salts of calcium bilirubinate were synthesized and analyzed chemically, crystallographically, spectroscopically, and by x-ray diffraction. All salts were found to be crystalline, and the intermediate salt, which has 1.5 molecules of bilirubin per calcium atom, probably has a crystal structure containing molecules of both acid and neutral salts. The acid or intermediate salts were found in 14 of 70 gallstones analyzed recently by x-ray diffraction.

8427 CALCIUM IN BILE AND CALCIUM SALTS IN GALLSTONES. (Eng.) Sutor, D. J.; Wilkie, L. I. (Dept. Chemistry, Univ. Coll., Gower St., London WC1E 6BT, England). *Clin. Chim. Acta* 79(1):119-127; 1977.

In the gallbladder and common duct bile from 21 patients undergoing cholecystectomy (usually because of gallstones), Ca was found to exist in at least two forms, bound Ca and ultrafilterable Ca. Ultrafiltration showed that some Ca was bound to substances with a molecular weight >10,000, and there was significantly less bound Ca ($p<0.002$) in common duct bile (1.20 ± 0.42 mM) than in bile from functioning gallbladders (3.89 ± 0.41 mM). The chief binding agent for Ca is likely to be the mixed micelle. There was a smaller amount of ultrafilterable Ca in common duct bile (1.16-1.61 mM) than in bile from functioning gallbladders (0.95-5.22 mM), but the difference was not significant. For patients with cholesterol or some Ca carbonate on the stone surface, ultrafilterable Ca concentrations covered a much narrower range (0.95-2.28 mM) than did the corresponding total Ca concentrations (2.40-9.70 mM). A comparison of ultrafilterable and total Ca values for different types of stone-formers showed that the deposition of Ca carbonate in gallstones was not related to any Ca measurement made. However, patients with some Ca phosphate and/or Ca bilirubinate on the stone surface had significantly more ultrafilterable Ca in their bile (3.62 ± 0.72 mM) than did patients with cholesterol stones (1.64 ± 0.11 mM, $p<0.002$) or patients with Ca carbonate stones (1.48 ± 0.14 mM, $p<0.01$).

8428 PREVALENCE OF HYPERLIPOPROTEINEMIA IN MEN WITH GALLSTONE DISEASE. (Eng.) Kadziolka, R.; Nilsson, S.; Schersten, T. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 12(3):353-355; 1977.

To determine whether there is a significant correlation between hyperlipoproteinemia and gallstone disease, the prevalence of hyperlipoproteinemia in a consecutive series of 46 male gallstone patients was compared with that in an age-matched consecutive series of 40 gallstone-free patients. Hyperlipoproteinemia was present in 43.5% of the gallstone patients as compared with 22.5% of the control patients ($p<0.05$). Prebeta-hyperlipoproteinemia (type IV) was the most common lipoprotein disorder in both the gallstone patients and controls.

8429 CHENODEOXYCHOLIC ACID THERAPY OF GALLSTONES. (Eng.) Dowling, R. H. (No affiliation given). *Clin. Gastroenterol.* 6(1):141-164; 1977.

Various aspects of chenodeoxycholic acid (CDCA) therapy of gallstones are discussed, and the indications for CDCA based on experience in treating >100 patients are outlined. Biliary colic is the most common symptom in cholelithiasis patients accepted for CDCA treatment; a history of pancreatitis, cholangitis, obstructive jaundice, and cholecystitis warrants cholecystectomy rather than a dissolution procedure. Patients with multiple, small, radiolucent gallstones in a gallbladder that opacifies well during cholecystography and contracts promptly in response to a fatty meal are most likely to benefit from CDCA treatment. The dose of CDCA should be a fixed amount per day related to body weight. Patients who received 14.4 ± 1.0 mg/kg showed dissolution of stones and their post-treatment saturation index (SI, numerical index of saturation of bile with cholesterol) was less than unity. However, in patients who received 10.6 ± 1.2 mg/kg, the stones remained unchanged in size and the mean post-treatment SI was greater than unity.

8430 IMPROVING CHOLECYSTECTOMY. (Eng.) Corlette, M. B.; Bismuth, H.; Hepp, J. (821 Massachusetts Ave., Arlington, MA 02174). *Am. J. Surg.* 133(6):655-657; 1977.

Bacteriologic studies of bile in 100 patients undergoing cholecystectomy for various manifestations of cholelithiasis were carried out, and a technique for reducing infection in cholecystectomy was tested in 200 patients. In the first 100 patients, there were 36 positive cultures. The frequency was greater in older individuals and in those with acute cholecystitis and common duct stone; these results are comparable to those in previous studies and reaffirm the septicity of the bile. The incidence of wound infection was only 0.5% in 200 patients in whom a water-impermeable wound drape was sewn to the peritoneum to prevent contamination by potentially infected bile. This result, in patients with an infectious risk comparable to that in other series, establishes the value of meticulous wound isolation in preventing wound infection.

8431 USE OF BILIARY DRAINAGE IN DIAGNOSIS OF BILIARY TRACT DISEASE. (Eng.) Sigman, H. H.; Goldberg, N.; Niloff, P. H.; Lachance, C. (Jewish General Hosp., Montreal, Canada). *Am. J. Gastroenterol.* 67(5):439-443; 1977.

A retrospective study was carried out in 35 patients with normal oral cholecystograms who underwent cholecystectomy on the basis of abnormal bile collected by duodenal drainage. The patients were found to have either cholesterol crystals, calcium bilirubinate pigment, or leukocytes in gallbladder bile collected through duodenal drainage. At cholecystectomy, the gallbladders all showed histological evidence of chronic cholecystitis and/or cholesterolosis. In addition, four gallbladders contained calculi. Cholecystectomy is recommended as treatment for a selected group of patients with duodenal bile crystals or pigment.

8432 DISTURBANCES OF BILE ACID METABOLISM IN CHOLESTASIS. (Eng.) Stiehl, A. (No affiliation given). *Clin. Gastroenterol.* 6(1):45-67; 1977.

Literature on the biochemical and clinical aspects of cholesterol-induced changes in bile acid metabolism is reviewed. Patients with cholestasis due to cirrhosis or biliary atresia have a markedly reduced total bile acid pool that is shifted from the enterohepatic circulation into the peripheral blood, liver, and other tissues. In cholestatic patients, bile acids such as 3β-hydroxy-5-cholenic acid, ursodeoxycholic acid, hyodeoxycholic acid, hyocholic acid, and trihydroxycoprostanic acid are detected in addition to the primary and secondary bile acids that predominate in healthy individuals. Since these bile acids are also detected in patients with complete or almost complete biliary obstruction, it is suggested that they are direct catabolites of cholesterol that do not necessarily originate from the bacterial degradation of cholic and chenodeoxycholic acids. In the serum of patients with cholestasis, only 10% to 20% of the bile acids are sulfated. A relatively low serum concentration and relatively high urinary excretion rates of sulfated bile acids (almost 50%, compared to 5-15% in normal subjects), might indicate that in these patients, organs other than the liver could contribute to the detoxification and excretion of possibly hepatotoxic bile acids.

8433 CELLULAR IMMUNITY IN INTRA- AND EXTRAHEPATIC CHOLESTASIS. (Ita.) Fargion, S. R.; Podda, M.; Cappellini, M. D.; Fiorelli, G. (Istituto di Clinica Medica III dell'Universita di Milano, Milan, Italy). *Minerva Gastroenterol.* 22(3):261-265; 1976.

In vivo and *in vitro* cellular immune reactions were determined in 17 patients with extrahepatic cholestasis and in 5 patients with primary biliary cirrhosis (PBC). Antimitochondrial antibodies (AMA) were determined by immunofluorescence. Intradermal reactivity was determined with purified protein derivative (PPD) and *Candida albicans* extract. Lymphocyte transformation in the presence of autologous and normal plasma was determined by tritiated thymidine incorporation. Fourteen healthy subjects served as controls. One hundred percent of patients with PBC were positive for AMA. Only 1.4% of the patients with extrahepatic cholestasis were AMA positive. Sixteen percent of patients with PBC and 17% with extrahepatic cholestasis were PPD positive, and 16% of PBC patients and 11% of patients with extrahepatic cholestasis were also *Candida* positive. Sixty-four percent of the controls were positive for PPD and 57% were positive for *Candida*. Autologous plasma reduced whereas normal plasma increased lymphocyte transformation in patients with both PBC and extrahepatic cholestasis. Plasma from PBC and extrahepatic cholestasis patients inhibited lymphocyte transformation in normal subjects. It is possible that plasma factors associated with cholestasis interfere with cellular immunity.

8434 NONOPERATIVE MANAGEMENT OF BILIARY DUCTAL STENOSIS: REPORT OF A MOST UNUSUAL CASE. (Eng.) McGill, C.; Aaron, W. S.; Polk, H. C., Jr.

(Univ. Louisville Sch. Medicine, Louisville, KY 40201). *Gastroenterology* 73(1):150-153; 1977.

The case of a 22-yr-old woman with documented iatrogenic stricture of the common duct is reported. A biliary-cutaneous fistula and a lengthy, tapering stenosis of the common bile duct were observed 4 weeks after the patient had undergone cholecystectomy for chronic cholecystitis. Although the presenting illness of the patient followed much of the usual pattern for biliary stricture, certain characteristics indicated a good prognosis. First, her common bile duct had been accurately identified. Second, her stenosis appeared to be at the site of T-tube insertion. Third, the lesion tended to be more smoothly tapering and longer than typical bile duct injuries. This last characteristic, together with the absence of jaundice and the low volume of the biliary fistula, pointed to a consideration of nonoperative treatment. The authors hypothesized that such a lesion could be associated with inflammation and edema in the choledochostomy suture line, both of which were likely to improve with time. No reconstructive operation has been done. The strictured segment has resolved so that the patient is completely asymptomatic and has no direct or indirect laboratory or radiographic evidence of biliary obstruction.

GENERAL

8451 ANATOMY AND RADIOLOGIC DIAGNOSIS OF PERIHEPATIC ABSCESSES. (Eng.) Whalen, J. P. (New York Hosp., 525 E. 68th St., New York, NY 10021). *Radiol. Clin. North Am.* 14(3):406-428; 1976.

Unfortunately, the morbidity and mortality of perihepatic abscesses are proportional to the time spent on diagnosis, and there is much confusion concerning the anatomy of the spaces of the upper abdomen. Therefore, an attempt was made to define and illustrate the spaces around the liver and to facilitate the radiologic diagnosis of the abscesses within these spaces. A simplified approach to the radiologic routine comprises plain films plus barium films of the stomach, duodenum, and colon in both the frontal and lateral projections. A brief description, accompanied by several radiographs, is given of the types of abscesses that can occur: right visceral abscesses (right paracolic or anterior visceral, midvisceral, posterior visceral), right subphrenic abscesses (anterior, porterior), left perihepatic abscesses (gastrohepatic recess, gastrosplenic recess, renosplenic, lesser sac), and left subphrenic abscesses.

8452 CHEMOTHERAPY OF MALIGNANT MAJOR SALIVARY GLAND NEOPLASMS: A 25-YEAR REVIEW OF M. D. ANDERSON HOSPITAL EXPERIENCE. (Eng.) Rentschler, R.; Burgess, M. A.; Byers, R. (M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Cancer* 40(2):619-624; 1977.

The clinical manifestations of malignant neoplasms of major salivary glands in 671 patients who received chemotherapy at one hospital during a 25-yr period were defined, and experience with single agent and combination chemotherapy was evaluated as a basis for possible prospective therapeutic trials. Thirty-six patients with advanced local or metastatic disease underwent 62 evaluable trials with a variety of chemotherapeutic agents, either alone or in combination. Six patients achieved a partial response, with a median duration of 3 months. Ten additional patients had stable disease for 2 or more months. Anthracyclines appeared to be the most effective agents in this study, with three partial responses of six evaluable trials. The longest partial response (10 months) occurred in a patient receiving combination chemotherapy plus *Bacillus Calmette-Guerin* immunotherapy. Pulmonary metastases were most commonly responsive to chemotherapy. The median intervals from diagnosis to death or to last follow-up and from initiation of chemotherapy to death or to last follow-up were 30 months and 6 months, resp. Further therapeutic trials are necessary before response rates to single chemotherapeutic agents or combinations can be accurately assessed. In view of the poor prognosis of patients with recurrent disease, postoperative adjuvant studies with chemoimmunotherapy in patients with a high risk of recurrence are planned.

8453 TREATMENT OF DIARRHEAL DEHYDRATION. (Eng.) Sperotto, G.; Carazza, F. R.; Marcondes, M. D. (Hospital das Clinicas, Caixa Postal 8091, Sao Paulo, Brazil). *Am. J. Clin. Nutr.* 30(9):1447-1456; 1977.

A regimen for the treatment of diarrheal dehydration that was developed in Sao Paulo, Brazil, where the incidence of diarrheal disease is 15 to 20% of pediatric hospital visits (approximately 13,000/yr), is presented. The estimated water, Na, and Cl deficit is replaced by an infusion of half-isotonic saline in 2.5% glucose over a 2- to 3-hr period. Fluid deficit can be estimated from clinical parameters or from recent weight records. This rapid fluid replacement does not cause convulsions or pulmonary edema in reasonably well-nourished children. Initiating treatment with 20 ml/kg of saline is preferred in marasmic, malnourished children. K deficit can be corrected by the administration of 2.5 mEq/kg (1 ml of 19.1% KCl solution) for 3-4 days. The routine use of Mg salts, phosphate salts, or biocarbonate is not recommended. Metabolic activity was estimated in 11 children to calculate fluid and electrolyte maintenance needs. Estimating the gain of endogenous metabolic water as approximately 10 ml/100 cal/24 hr, water replaced at the rate of 100 ml/100 cal/24 hr with 3 mEq Na/100 cal/24 hr appeared to maintain urine excretion as an optimal osmolal concentration.

8454 Escherichia coli SEROTYPES THROUGHOUT THE GASTROINTESTINAL TRACT OF PATIENTS WITH INTESTINAL DISORDERS. (Eng.) Tabaqchali, S.; Howard, A.; Teoh-Chan, C. H.; Bettelheim, K. A.; Gorbach, S. L. (St. Bartholomew's Hosp., London, EC1A 7BE, England). *Gut* 18(5):351-355; 1977.

O and H antigen serotyping was performed of *Escherichia coli* present along the entire length of the gastrointestinal tracts of nine patients with bacterial overgrowth of the small intestine. Multiple serotypes and biotypes were represented, although usually a single serotype predominated in each patient. In a number of cases, the different O:H serotypes were antigenically related, indicating that antigenic degradation was occurring. The serotypes isolated from the stomach and small intestine were represented in the feces. In one patient, 6 weeks after p.o. tetracycline therapy, a recolonization of the small bowel with different serotypes of *E. coli* than those observed before antibiotic treatment was observed. Food did not have an effect on serotypes isolated. Fasting and postprandial samples of *E. coli* from four patients yielded similar serotypes, even though food had caused a marked increase in the *E. coli* viable counts and also led to the appearance of the anaerobic *Bacteroides sp.* for the first time in the intestinal aspirates from one patient. In general there appears to be a stable bacterial ecosystem in each patient that may require specific p.o. antibiotics for its alteration.

8455 A STUDY OF THE PREVALENCE OF ROTAVIRUS INFECTION IN CHILDREN WITH GASTROENTERITIS ADMITTED TO AN INFECTIOUS DISEASES HOSPITAL. (Eng.) Birch, C. J.; Lewis, F. A.; Kennett, M. L.; Homola, M.; Pritchard, H.; Gust, I. D. (Fairfield Hosp. for Communicable Diseases, Melbourne, Victoria, Australia). *J. Med. Virol.* 1(1):69-77; 1977.

Evidence of rotavirus infection was sought in 400 fecal specimens from children with gastroenteritis in Melbourne, Australia. Rotavirus was found in 41.7% of the specimens. This virus was detected more often during the winter months, particularly in children aged between 12 months and 3 yr. Detection of rotavirus by electron microscopy was more sensitive than detection by counterimmunoelectrophoresis. Routine bacterial and viral studies revealed that bacterial pathogens (*Salmonella* and *Shigella*) and common enteric viruses were associated with relatively few cases of gastroenteritis. There is little doubt that rotavirus is the most important etiological agent of acute gastroenteritis in young children in Melbourne.

8456 GASTROENTERITIS AND HUMAN REOVIRUS-LIKE AGENT INFECTION DURING THE 1975-76 OUTBREAK: AN ELECTRON MICROSCOPIC STUDY. (Eng.) Brandt, C. D.; Kim, H. W.; Rodriguez, W. J.; Arrobio, J. O.; Kapikian, A. Z.; Wyatt, R. G.; *et al.* (Children's Hosp., 2125 13th St., N.W., Washington, DC 20009). *Clin. Proc. Child. Hosp. Natl. Med. Cent.* 33(2):21-26; 1977.

The stools of 145 infants and children with gastroenteritis (hospitalized during a gastroenteritis epidemic between July, 1975 and June, 1976), 76 outpatients with diarrhea, and 257 controls were examined ultrastructurally for the presence of a human reovirus-like agent (HRVLA). HRVLA was found in the stools of 43.4% of the 145 infants and young children with gastroenteritis. HRVLA infections were detected between December 10, 1975 and May 24, 1976. During January, the peak epidemic month, 88.4% of 43 inpatients with gastroenteritis and 78.9% of 19 outpatients with gastroenteritis were found to be infected with this virus. For the third successive epidemic year, the recently described HRVLA has been a major cause of pediatric "winter" gastroenteritis in Washington, DC.

8500 HYDATID DISEASE IN NEW ZEALAND: AN EPIDEMIOLOGICAL STUDY OF TRANSMISSION AMONG MAORIS. (Eng.) Burridge, M. J.; Schwabe, C. W. (Coll. Veterinary Medicine, Box J-125, JHMHC, Univ. Florida, Gainesville, FL 32610). *Am. J. Trop. Med. Hyg.* 26(2):258-265; 1977.

An epidemiological study was designed to determine the factors placing the Maori people of New Zealand at an unusually high risk of infection with *Echinococcus granulosus*. Using stepwise multiple regression techniques, it was shown that the most important determinant of the incidence rate of human hydatid disease was the proportion of Maoris in the local population. The Maori system of land tenure, based on the Maori land laws, led to the formation of many small fragmented properties under multiple ownership, decreasing the incentive of individual Maori farmers to improve their farming methods. In addition, long-standing behavioral patterns, such as an easy familiarity with working dogs and the feeding of dogs on raw offal, were practices that changed slowly, thus contributing to the maintenance of high *E. granulosus* prevalence in dogs owned by Maoris. These cultural and behavioral factors, together with poor dog control, exposed all members of the rural Maori community to an increased risk of infection with *E. granulosus*, resulting in a strikingly higher incidence rate of hydatid disease for all age-groups and for both sexes among Maoris than among non-Maoris.

Regional Enteritis

8507 FURTHER OBSERVATIONS ON THE TRANSMISSIBILITY OF CROHN'S DISEASE. (Eng.) Mitchell, D. N.; Rees, R. J. W. (Brompton Hosp., London, England). *Ann. N.Y. Acad. Sci.* 278:546-559; 1976.

To further investigate the possible existence of a transmissible factor in Crohn's disease, normal and immunologically deficient CBA mice were inoculated i.p. or i.v. with whole fresh, fresh autoclaved, fresh supernatant, or filtered supernatant of whole Crohn's or non-Crohn's homogenate prepared from fresh unfrozen gut or mesenteric lymph node tissue into footpads. Epithelioid and giant cell granulomas were present in a substantial proportion of the footpads and in the bowel or mesenteric lymph nodes of a proportion of mice given each fresh Crohn's homogenate b any of these routes 15-17 months after inoculation, but were not present in mice given non-Crohn's or autoclaved Crohn's homogenate. Successful passages were achieved following the inoculation of Crohn's mouse tissue homogenates, including passage from mice receiving filtered supernatant (0.2 μ) or whole Crohn's homogenate, into footpads or i.v. The epithelioid and giant cell granulomas evolved slowly over a period of many months following the inoculation of Crohn's tissue or passage homogenates and persisted thereafter. The transmissible agent is inactivated when homogenate from Crohn's tissue is autoclaved, can be passaged successfully into footpads or i.v., and has been shown to pass an 0.2-μ membrane filter. It is therefore presumably viable and must approximate to the size of a virus or be capable of being deformed to pass a filter of this pore size.

8508 RECTAL POTENTIAL DIFFERENCE AND HISTOLOGY IN CROHN'S DISEASE. (Eng.) Ruddell, W. S. J.; Blendis, L. M.; Lovell, D. (Central Middlesex Hosp., London, England). *Gut* 18(4):284-289; 1977.

Rectal potential difference (PD) was measured at 10 cm from the anus in 27 patients with Crohn's disease and in 16 subjects without gastrointestinal disease (controls) to establish a normal range. The rectal PD in the 16 controls ranged from 28 to 48 mV, with the mean value being 38 ± 3 mV (mucosa negative to serosa). The PD was significantly lower in six patients with sigmoidoscopically active rectal Crohn's disease (17 ± 3 mV) than in Crohn's patients with normal sigmoidoscopic appearances (36 ± 2 mV, $p<0.01$), Crohn's patients with an abnormal but inactive mucosa (40 ± 2 mV, $p<0.01$) and controls (38 ± 3mV, $p<0.01$). The rectal PD in six Crohn's patients whose biopsies showed abnormalities of the superficial epithelium (18 ± 4 mV) was significantly lower than that in Crohn's patients with normal histology (37 ± 2 mV, $p<0.01$) and in patients whose histological abnormalities were restricted to the lamina propria and glands (39 ± 2 mV, $p<0.01$). Excluding patients with sigmoidoscopically active rectal Crohn's disease, the mean rectal PD in 6 Crohn's patients with diarrhea (29 ± 3 mV) was significantly lower than that in 15 Crohn's patients with normal bowel habits (41 ± 2 mV, $p<0.01$) and in controls ($p<0.01$). When the response of rectal PD in 13 patients with Crohn's disease was assessed in relation to mineralocorticoid stimulation with p.o. fludrocortisone (0.1 mg every 8 hr for 6 doses), the PD failed to rise significantly only in 3 patients with sigmoidoscopically active disease and in 3 patients who had severe superficial epithelial abnormalities in their rectal biopsies. Response to fludrocortisone proved to be a less sensitive indication of minor mucosal abnormalities than sigmoidoscopy or biopsy.

8509 THE DILEMMA OF CROHN'S DISEASE: ILEODUODENAL FISTULA COMPLICATING CROHN'S DISEASE. (Eng.) Wilk, P. J.; Fazio, V.; Turnbull, R. B., Jr. (Downstate Medical Center, State Univ. New York, Brooklyn, NY). *Dis. Colon Rectum* 20(5): 387-392; 1977.

The surgical management of nine cases of ileoduodenal fistula complicating Crohn's disease is reported. Because an attempt at primary closure of the duodenal defect may fail, the treatment of choice was formal cross-cut two-layered duodenojejunal anastomosis with extensive drainage of the area postoperatively. Five patients underwent duodenojejunal anastomosis, resection of the terminal ileum, subtotal colectomy, and ileostomy for Crohn's ileocolitis with ileoduodenal fistula; two patients underwent duodenojejunal anastomosis, resection of the terminal ileum and right colon with ileotransverse colon anastomosis, and segmental resection of the sigmoid with colocolonic anastomosis for ileitis with ileoduodenal and ileosigmoidal fistulas; one patient underwent duodenojejunal anastomosis and resection of the terminal ileum and right colon with ileocolonic anastomosis for ileitis with ileoduodenal fistula; and one patient underwent closure of the duodenal fistula, subtotal colectomy, and ileostomy for ileocolitis with ileoduodenal fistula. The inflammatory nest in the right upper quadrant was drained extensively with Penrose drains in every case. There was no postoperative mortality, and only three patients had postoperative complications (mild pneumonia, urinary tract infection, blood clot from bleeding omental vessel). All nine patients have been followed for 6 months to 10 yr and are well with no late recurrence of duodenal fistula. Five patients have needed reoperation for recurrent Crohn's disease of the ileum or colon.

8510 POSSIBLE SIGNIFICANCE OF PROSTAGLANDINS IN THE PATHOGENESIS OF CROHN'S DISEASE. (Ger.) Schmidt, E.; Bruch, H. P.; Walter, K. (Chirurgische Universitatsklinik, Josef-Schneider-Strasse 2, D-8700 Wurzburg, W. Germany). *Chirurg* 48(4):254-255; 1977.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.
